The Section of School Hygiene, which merges both into that of the Care of Defectives and that of Physical Training, is of vast interest. The Board of Education has set up maps and charts showing the administrative control exercised over the health of the young. The effect of the introduction of the Medical Inspection Act of 1907 is clearly shown, and the distribution of the special schools forms a key to the remainder of the exhibit. Numerous methods of dealing with the defective are exhibited, and in many cases the results of the method employed are pictorially demonstrated. The London County Council has a large and particularly fine exhibit. Every phase of school life, in its relationship to the health and development of the children, is illustrated in a most striking manner. The teaching of trades under favourable circumstances, the organisation of games, and the methods adopted in the open air and other special schools are dealt with in detail. In Edinburgh markedly good results are obtained in the education of deaf mutes by housing them together with normal hearing children. The effect is that the children gain in intelligence rapidly until there is scarcely any difference between the defective and the normal children. Speaking appears to come much earlier than is usual by other methods and the children rapidly become cheery and happy. These results are depicted by the managers of the Donaldson Hospital. Equally interesting are the effects of careful education, care of the health, and physical training on wastrels in the hands of the authorities at Dr. Barnardo's Home. A series of clear photographs show the methods and results in this Home. A dental school clinic, set up under the guidance of the British Dental Association, should demonstrate that every school authority can afford to look after the teeth of the children attending the schools. The total equipment, which is adequate in every particular, costs only £50.

Dr. R. W. Philip has set up an elaborate exhibit illustrating the scheme for the combating of tuberculosis adopted in Edinburgh. The success of this scheme depends chiefly on the care of every patient, no matter what stage of disease he may harbour. By means of tables, charts, and excellent photographs this scheme is rendered clear. The control of milk, as far as tubercle bacilli are concerned and the tracing of possible foci of infection, has received minute attention at the hands of Professor S. Delépine, and his exhibit is a pattern of excellence. From a technical point of view it is difficult to imagine a more wonderful series of large section of lung than those sent by Professor G. Sims Woodhead, dealing with the pathology of the various types of tuberculous affections. His opaque sections, too, which demonstrate the avascular nature of tuberculous lesions, command universal admiration. In the Tropical Section Professor G. H. F. Nuttall's extraordinary collection of disease-carrying ticks, the only complete collection in the world, is set up in such a manner that the student learns much about the ticks and the parasites which each carries. The Liverpool School of Tropical Medicine has prepared a case dealing with malaria, sleeping sickness, yellow fever, myiasis, and three-day fever. The individual items are excellently mounted and the whole is teeming with interest both for the public and for the expert. The Metropolitan Asylums Board has lent some highly interesting models for exhibition. The training ship *Exmouth*, shown in the Section of Physical Training, the North-Western Fever Hospital, the Brook Fever Hospital, and the ambulance steamer are all excellent in their own way. An interesting series of photographs illustrating the life, work, and recreation of the English hospital nurse attracts considerable attention. The pictures have been specially prepared under the guidance of the matrons of several of the large London hospitals, and depict in a most natural manner the nurse performing a number of her duties.

Some peculiar models of Indian hospitals have been lent by the various missionary societies, that of the Peshawar Hospital, that of the Neyoor Hospital, and that of the Union Medical College in Peking being chiefly worthy of notice. An exhibit, in model form, shows a Hindu woman being treated by a native quack under distinctly unhygienic conditions, and a Mohammedan lady being attended to by a crowd of friends and relatives, also under unfavourable

conditions, in contrast with the treatment in a missionary hospital, where modern methods are employed. On the whole, it is apparent from the section that the condition of medical treatment among the native population of India, and to a certain extent in China, to-day is in much the same condition as medical treatment was in Europe some 300 years ago. The Church administers medical as well as spiritual treatment, and even if the medical woman who acts as physician or surgeon possesses the skill and knowledge common to the medical world in the West, the surroundings and the caste difficulties are so great that the comparison with olden times is not quite unjustified.

In the Town Planning Section the various exhibitors have struggled hard with one another in their effort to send the best exhibit. Each in its special way commands a special preference, and each deserves a detailed description or careful study. It is noteworthy that in the Liverpool exhibit the selected insanitary dwellings shown have been completely demolished, and improved dwellings have been set up in their place. In the Manchester exhibit insanitary dwellings are shown which have been saved and rendered hygienic by judicious alterations. In the same way, in the town planning part, some of the exhibitors show ideal plans which appear to have little consideration to the rent necessitated, while others do the best that can be done for little money. In view of the recent discontent in the Bourneville industrial colony the exhibit sent thereof gains in interest not inconsiderably.

The Disposal of Sewage Section teems with interesting material. The methods of disposal are depicted by diagram and by transparency, and a marvellous model of London showing the various levels of the sewers in regard to the river level tells its story more eloquently than any photograph. The immense size of the outfall sewers is shown in photographs by comparison with the size of the workmen busy in them or on them. A highly interesting and important exhibit is that of Dr. A. C. Houston dealing with the analysis of London water and the number of bacteria contained therein. In connexion with this mention should be made of his excellent series of slides illustrating the tracing of anthrax bacilli throughout the sewage, sludge, &c., during an epidemic in Yeovil. The pavilion is lavishly supplied with transparencies which are illuminated by electric light shining through opal glass. The details of each picture are enormously improved by this method of illumination, and the visitor is able to see microscopical appearances clearly without the aid of a microscope.

Only a few of the exhibits have been mentioned, but these few will show that the section contains a great deal of scientific importance and interest, and that it is worthy of careful study. The exhibition will remain open until the end of October and a visit to it will never be forgotten. We propose to publish short descriptions of some of the more important scientific sections of the exhibition in a subsequent number, in order to give the reader some idea of the nature and scope of the undertaking upon which those who have been responsible for it are most heartily to be congratulated.

MEDICINE IN SCANDINAVIA.

No. III.—SWEDEN.[1]

Number of Medical Men.—Medical Education.

SWEDEN, with an area of 170,713 square miles, had at the end of 1909 a population of 5,476,441. The medical men numbered 1502, giving a ratio of 1 to 3646 inhabitants. This relative scarcity of medical men is due to many causes, one of which is the length of the medical curriculum, which occupies on an average eight years. There are two important examinations. Part I. includes anatomy, physiology, chemistry, pharmacology, and histology. Part II. includes clinical medicine, surgery, obstetrics, gynæcology, pathological anatomy, and medical jurisprudence. There is also a special examination in hygiene and syphilis. The cost of the medical education is estimated at £1000. The quality of the teaching is high, and the reputation for professional ability which the Swedish medical men possess is fully deserved.

[1] Nos. I. and II. were published in THE LANCET of July 1st (p. 36) and 8th (p. 114), 1911, respectively.

The Evolution of Medicine in Sweden.

The evolution of the medical profession has followed lines similar to those of other European countries. Before the seventeenth century the practice of medicine was in bad repute, and was largely in the hands of foreign adventurers. In the seventeenth century the profession was represented by physicians whose training was largely academic and unpractical, and by barber surgeons whose calling was a handicraft learnt under a master on the battlefield and in the barber's shop. In 1663 the Collegium Medicorum was founded by the physicians and held an official position as an examining body, and as a body controlling medical practitioners. At about the same time the Societas Chirurgica was founded by the surgeons and existed as a rival of the Collegium until 1797, when the two bodies were united under the title of Collegium Medicum. The first to place the profession on an honoured and scientific footing were Carl von Linné, the botanist, and Nils Rosen von Rosenstein in the eighteenth century, and the standard then set has been at a high level ever since.

Medical Societies.

There are to-day two medical societies. Of these, Svenska Läkaresällskapet is a society devoted chiefly to literary and scientific work. Its origin dates from 1807, when it was formed in Stockholm by seven of the leading medical men of that period. The history of this society, published in connexion with its centenary celebration, is largely a history of the whole medical profession, and it therefore makes interesting reading. During the Napoleonic wars it led a precarious existence, for many of its leading members were obliged to devote all their energies to the training of army surgeons in response to the sudden demands made for Swedish surgeons by the Government. The liberties, too, of the scientific press were much curtailed at this period, and English, French, and other foreign medical books were smuggled into the country only at rare intervals. In spite of these difficulties the society kept its head above water, and its publications during the last century have been both numerous and valuable. Its official organ, *Hygiea*, is a monthly journal which ranks as the best medical journal in Sweden. The society's library is now a large one, and includes 135 periodicals.

Organisation of the Medical Profession.

Allmänna Svenska Läkarföreningen (the General Swedish Medical Association) is a society formed in 1902 to safeguard the professional interests of medical men, its functions as a scientific body being of secondary importance. Its membership in 1910 had risen to 1081, and its branches spread throughout the country. The rules of the association resemble those of the corresponding bodies in Norway and Denmark, their aim being: (1) the maintenance of good feeling between medical men and the furtherance of their social and economic interests; and (2) the cultivation of scientific interests among medical men. It is at present too early to judge of the association's value to the profession, but numbering, as it already does, more than two-thirds of the practitioners in Sweden, it cannot fail to have a far-reaching influence on their future position, and through them on sanitary reforms throughout the country. It is strange that the association should have been formed so much later than similar bodies in Norway and Denmark. It is possible that the need for such a society was less felt in Sweden, where the Svenska Läkaresällskapet already, to a certain extent, protected medical interests, and where there was less competition between the members of the profession than elsewhere in Scandinavia.

Medical Schools.—Government Appointments.

There are three medical schools—Upsala, Lund, and the Karolinska Institute in Stockholm. Government medical officers are numerous and include the following. Inspectors of hygiene for each province, of which there are 24. Under these there are 139 ordinary district medical officers and 162 extraordinary district medical officers. The medical officers of asylums are also Government officials. The salaries of district medical officers range from £180 to £236, and a pension of £222 is given at the age of 60. Although asylums are owned and managed by the State, general hospitals are as a rule erected and maintained by the county councils. The sanitary medical officers of the towns are also appointed and paid by the local authorities.

Campaign against Tuberculosis.—Unqualified Practice.

The tuberculosis campaign is carried on vigorously both by the medical profession and by the nation generally. Large sums of money have been obtained and spent on educative and sanatorium lines. It is a striking feature of the Scandinavian countries that, once the needs for sanitary reforms are clearly proved by responsible men, the work of reform is taken up wholeheartedly by the entire population. As an instance of this may be cited the popularity of the tuberculosis stamps which are affixed to letters, and which are sold in enormous quantities to rich and poor alike for the benefit of the consumptive poor. The "Maiblomst" or May flower (which costs 1 öre to make and 10 öre to buy) is seen everywhere on May 1st, and is a valuable source of income to the tuberculosis leagues.

The campaign against quackery has been fought both by medical men and chemists. A society with its headquarters at Upsala exists for the investigation of secret remedies and the exposure of the more blatant frauds, and under the guidance of Professor Mörner it has become a powerful weapon against the quack adventurer. Details of this society's work have already been given in THE LANCET of August 7th (page 419), 1909.

General Remarks on Medical Education in Scandinavia and other Matters.

Although, as has been shown, there are certain wide differences in the three Scandinavian countries with regard to medical education and conditions of practice, there are numerous features common to all. Thus the medical training is in every case thorough and practical. Sweden's three medical schools all require a high standard of proficiency in their graduates, and the Universities of Christiania and Copenhagen are the only examining bodies in their respective countries. The uniformity of education and graduation which is thus attained compares favourably with the conditions existing in other countries, such as England and the United States, where the value of a medical degree is a variable quantity and a source of mystification to the general public. Special qualifications and diplomas are conspicuous by their absence, but the graduate in medicine may (with certain restrictions) proceed to the degree of M.D., the tests for which are severe, so that its possessors are relatively few in number, and limited mainly to those who are enabled to devote considerable time to research work. The Scandinavian degree of M.D. is therefore far superior to many continental and American degrees.

The right to practise medicine is jealously guarded, and the foreigner who would practise in Scandinavia must either pass the examinations of the respective countries or else practise as a quack at his own risk; and the pitfalls which the paternal Governments of the three countries have prepared for the quack who endangers the lives of patients are sufficiently numerous to make any extensive practice a danger to the unregistered person. Certain few exceptions have, however, from time to time been made in favour of practitioners with foreign degrees wishing to practise without passing the examinations of the country.

In all three countries the Teutonic influence is traceable everywhere, and is far in excess of that of any other country. German text-books are the most popular. Some of the Scandinavian medical journals also give German or French *résumés* of their original articles. Germany, too, is the Mecca of the Scandinavian medical pilgrim, and a course of post-graduate study is frequently taken in Berlin or some other German town. The expenses of such courses are frequently defrayed by travelling scholarships, which are numerous in proportion to the wealth of the Scandinavian countries. Post-graduate studies are also encouraged at home.

The extent to which medical practitioners may advertise themselves varies not only in the different countries, but in Denmark it also varies in different localities, according to the rules of each branch of the Medical Association; but on the whole, greater freedom is allowed than in England; and in Norway, for example, the medical practitioner may advertise in the lay press, publishing his name, his specialty (if any), and his address and hours at home. But if, for instance, he were to advertise himself as a specialist in urinary surgery on the strength of having performed a couple of circumcisions his colleagues would soon take him to task. The freemasonry which exists among Scandinavian medical men is also extended to the stranger, and medical visitors to these northern countries may always be sure of finding that the words "Kollega" and "Kollegialitet" are not merely polite phrases.

The author is indebted to Dr. Buhre, secretary of Allmänna Svenska Läkarföreningen, for much useful information about medical practice in Sweden.

METROPOLITAN HOSPITAL SUNDAY FUND.

THE following are among the amounts received at the Mansion House up to July 15th (total available for distribution £42,800):—

	£	s.	d.
St. Michael's, Chester-square	672	0	0
St. Peter's, Eaton-square, with St. John's, Wilton-road	462	0	0
St. Mark's, North Audley-street	293	0	0
St. Margaret's, Westminster	160	0	0
St. Mary's, Bryanston-square	157	0	0
St. Paul's, Portman-square	131	0	0
Christ Church, Mayfair	104	0	0
St. Stephen's, South Kensington	96	0	0
St. Bartholomew's, Sydenham	93	0	0
St. Michael's, Paddington	89	0	0
All Souls', South Hampstead	84	0	0
St. John's Presbyterian Church, Forest Hill	77	0	0
St. John's Wood Presbyterian Church	65	0	0
St. John's, Bromley, Kent	59	0	0
St. Saviour's, Cadogan-square	45	0	0
St. Saviour's, Denmark Hill	41	0	0
Dutch Church, Austin Friars	41	0	0
St. John's, Redhill	40	0	0
Hornchurch Parish Church	40	0	0
Metropolitan Tabernacle	40	0	0
Waltham Abbey Parish Church	35	0	0
St. James's, Holloway	34	0	0
St. Mary's, Newington, with St. Gabriel's	34	0	0
Highbury Quadrant Church	31	0	0
St. Mark's, Kennington	29	0	0
St. Agnes, Kennington Park	29	0	0
St. Olave's, Woodberry Down	28	0	0
St. Luke's, Hornsey	28	0	0
St. Saviour's, Brixton	27	0	0
St. German's, Blackheath	27	0	0
St. Olave's, Hart-street	26	0	0
Camden Church, Camberwell	26	0	0
St. George's, Campden Hill	26	0	0
St. Mark's, Surbiton	26	0	0
St. Peter's, Clerkenwell	25	0	0
All Saints', Notting Hill	25	0	0
Trinity Presbyterian Church, Clapham-road	25	0	0
St. George's, Brondesbury	24	0	0
St. Dunstan's, East Acton	24	0	0
St. Andrew Undershaft	23	0	0
Christ Church, Southgate	22	0	0
St. Paul's, Mill Hill	22	0	0
St. Mary's, Cuddington	21	0	0
St. Mary's, Peckham	20	0	0

BRITISH MEDICAL BENEVOLENT FUND.

AT the June meeting of the above Fund 25 cases were considered, and grants amounting to £183 made to 23 of the applicants. Appended is an abstract of the cases relieved:—

Wife, aged 43, of M.R.C.S., L.S.A., who has been incapacitated for some time past and is at present in an asylum. Has supported herself by typewriting, but owing to the removal of her employer has been obliged to accept a very indifferently paid post. Voted £5.

Widow, aged 78, of L.R.C.P. Edin. Only income a small annuity, which is insufficient to meet quite unavoidable expenses. Voted £12.

Widow, aged 39, of M.B., Ch.B. Edin. Lost her husband a few months ago after a long and expensive illness. Income £17 10s. per annum and hopes to support herself and her delicate mother by establishing a small business. Voted £5.

Daughter, aged 66, of late L.F.P.S. Glasg. Has maintained herself for several years by dressmaking, but now, on account of ill-health, is obliged to depend on letting rooms. Is allowed £10 a year by Hutcheson's Hospital. Voted £5.

Widow, aged 53, of M.R.C.S. Quite unprovided for at recent death of husband from new growth and is at present not well enough to support herself. Voted £10.

Daughter, aged 58, of M.D. Edin. Takes boarders if able to obtain them and receives slight help from friends. Voted £5.

Daughter, aged 32, of late M.R.C.S. Gave up a situation as governess a year ago to nurse her father, recently deceased, and spent all her savings on him. Now asks for help to purchase a suitable outfit for another post abroad which she expects to obtain. Voted £10 if situation is obtained.

Widow, aged 43, of L.R.C.P. Is endeavouring to get her two daughters elected to St. Anne's School and asks for a little help towards expenses of canvassing. Voted £5.

Daughter, aged 68, of late M.R.C.S. Supported herself by teaching for 43 years and now only able to do a little knitting. Relieved three times, £36. Voted £12.

Widow, aged 60, of L.R.C.P. Lond. Supports herself by letting rooms, but asks for help towards expenses of training her daughter in domestic economy. Relieved four times, £20. Voted £5.

Daughter, aged 54, of late L.R.C.P. Edin. Has for several years been quite unable to do any remunerative work on account of continued ill-health, and is entirely dependent on two younger sisters who have to support themselves. Relieved six times, £56. Voted £10.

Daughter, aged 58, of late M.D. Edin. Is a governess by occupation, but at present has no post, and endeavours to support herself by sewing. Relieved nine times, £45. Voted £5.

Widow, aged 61, of M.D. St. And. No income; lets lodgings. Children unable to help. Relieved seven times, £84. Voted £12.

Daughter, aged 60, of late M.R.C.S. Is allowed 5s. a week by friends and earns about the same by needlework. Eyesight failing. Relieved four times, £54. Voted £10.

Widow, aged 64, of L.R.C.P., L.R.C.S. Edin. Has endeavoured to support herself since husband's death, 15 years ago, by taking boarders, but is now in bad health, and dependent upon a sister and a daughter who is an elementary school teacher. Relieved four times, £39. Voted £5.

Daughter, aged 39, of late M.R.C.S. For some time had a post as shorthand-typist at an institution, but was obliged to leave when the staff was reduced, and has been unable to obtain another situation. Relieved once, £5. Voted £5.

Widow, aged 65, of L.F.P.S. Glasg. Quite unprovided for at husband's death several years ago, and has tried to maintain herself by nursing, but is in very feeble health. Receives £10 a year from the Hutcheson Hospital and slight help from friends. Relieved seven times, £70. Voted £10.

Daughter, aged 55, of late M.R.C.S. No income; health only allows of occasional light work. Relieved five times, £50. Voted £10.

Daughter, aged 50, of late M.R.C.S. Had to give up a post owing to temporary ill-health and requires a little help whilst seeking fresh work. Relieved five times, £30. Voted £5.

Deserted wife, aged 50, of M.R.C.S. Maintained herself by nursing for some years, but is now in indifferent health. Slight help from daughters. Relieved four times, £13. Voted £5.

Widow, aged 33, of L.S.A. Supports herself by private nursing, but has been incapacitated since a severe attack of influenza four months ago. Three children, of whom two are at St. Anne's School. Relieved three times, £25. Voted £10.

Daughter, aged 70, of late L.R.C.P. Edin. Has maintained herself by teaching for many years. No income. Relieved once, £12. Voted £12.

Widow, aged 60, of M.D. Edin. Has taken resident patients, but now, owing to a breakdown in health, is in serious difficulties. Relieved once, £10. Voted £10.

Contributions may be sent to Dr. Samuel West, the Honorary Treasurer, 15, Wimpole-street, London, W.

THE LONDON COUNTY COUNCIL AND MEDICAL CLINICS.

A SOMEWHAT remarkable report was submitted to the Education Committee of the London County Council on July 19th. It will be remembered that the Board of Education has only sanctioned the existing agreements with hospitals for the medical treatment of school children on condition that grave defects in the present scheme should be remedied. The Children's Care Subcommittee reported on July 19th, mentioning the arrangements that have been made for ensuring that children selected for treatment actually attended the hospitals, and adding that, pending the consideration of other points raised by the Board, the amount of accommodation to be provided by the Council and the institutions to be used were matters which could be settled independently. Accordingly the subcommittee recommended the renewal, subject to the consent of the Board of Education, of existing agreements to provide for the treatment of a maximum of 55,902 children at a cost of £15,264.

The Children's Care Subcommittee gave the following list of institutions proposed to be brought into the scheme, although in some cases the negotiations are not completed:—

North of Thames.	*South of Thames.*
Fulham Medical Treatment Centre.	Woolwich Medical Treatment Centre.
Hammersmith Medical Treatment Centre.	Deptford Children's Health Centre.
St. Pancras Medical Treatment Centre.	Lewisham Medical Treatment Centre.
Islington Medical Treatment Centre.	Camberwell Medical Treatment Centre.
Hackney Medical Treatment Centre.	Bermondsey Medical Treatment Centre.
Poplar Medical Treatment Centre.	Battersea Medical Treatment Centre.
St. Mary's Hospital, Paddington.	Royal Eye Hospital, St. George's-circus.
Charing Cross Hospital.	Belgrave Hospital for Children.
Metropolitan Ear, Nose, and Throat Hospital.	Miller General Hospital.
Hospital for Sick Children, Great Ormond-street.	
Royal London Ophthalmic Hospital.	
The London Hospital.	

The subcommittee claimed that the institutions were so distributed that practically every child (except in ringworm cases) would be able to obtain treatment within two miles of its home. Modifications had also been made to secure that the children should pass through the hospital routine apart from other patients, and that the amount paid by the Council specifically for the services of the medical men should be paid to them.

In the course of an interesting discussion it was stated that those members of the Education Committee who favour the establishment of school clinics had accepted the present proposals as the most satisfactory substitute. An amendment was moved that one clinic under the control of the Council be included in the list of treatment centres in order that there might be a check on the cost of treatment. On the ground that the National Insurance Bill would greatly modify the whole system of medical treatment of school children, and that the Council would be ill-advised, therefore, to set up any official machinery for the conduct of a clinic, the amendment was defeated. The proposed negotiations with hospitals were then agreed to.

At the same meeting of the Education Committee it was intimated that on July 25th the General Purposes Committee will recommend the Council to deal with the vexed question of the relations of the Public Health Department and the department of the medical officer (education) by placing the whole of the school medical work, including the organisation and administration of medical inspection and treatment of children and the work relating to the cleansing of children (with the staff employed on such work) under the direction of the Council's medical officer of health.

ASYLUM REPORTS.

Surrey County Lunatic Asylum at Netherne (Annual Report for the Year 1910).—At this asylum the average number resident was 675. Admissions numbered 264, and of these 96 were males and 168 were females. Forty-three patients were discharged recovered. The deaths numbered 61, and post-mortem examinations were made in 42 cases. It appears that a villa has now been opened for the reception of idiot children, and all of this class have been transferred from Brookwood.

Barnwood House Hospital for the Insane (Annual Report for the Year 1910).—At this hospital the average daily number on the register was 151. Thirty-nine patients were admitted. The discharges numbered 30, and 11 of these were discharged recovered, this being a percentage of 28·2 per cent. calculated on the total admissions, and 47·8 per cent. on the direct admissions. The average duration of residence of those who recovered was 2½ years. The deaths numbered six, the rate calculated on the daily average number resident being 3·9 per cent. Dr. J. G. Soutar, the medical superintendent, writing on the subject of making insanity a ground for divorce, remarks that one of the great aids to recovery was the knowledge that patients possessed that they would on recovery be welcomed back to their old places at home. He feels as a physician that it is impossible in a great many cases to give an opinion as to whether a patient will or will not recover, and that the contemplation of the possibility of the rupture of home ties would add to the misery of most, and deprive not a few patients of their chance of recovery. Dr. Soutar also makes wise remarks upon the necessity for careful scrutiny of the physical condition of mental patients. It is too often an obvious fault in asylum administration that the number of medical officers is wholly inadequate to perform their medical duties, and we are glad to note Dr. Soutar's opinion that properly to carry out details of treatment the same care and consideration is required in the treatment of many mental patients as is demanded from the physician who is treating enteric fever or pneumonia. Of seclusion Dr. Soutar writes that, in his opinion, if it be ordered with the same sense of responsibility which a physician feels when he prescribes a potent drug it is a beneficent mode of treatment. With this we are in entire agreement, and we would hope that in time seclusion should come to be regarded, not as a penal matter, but as a method of treatment of value in appropriate cases.

Worcestershire Asylum, Barnsley Hall, Bromsgrove (Annual Report for the Year 1910).—At this asylum the total number of cases admitted was 171. Of these 68 were males and

103 were females. The average daily number on the register was 532. Of the cases that were discharged 30 had recovered, giving a percentage of 21·1 on the direct admissions. Dr. Percy T. Hughes, the medical superintendent, considers it to be altogether misleading to discharge under the head of "recovered" those patients in whom the acute attack has caused obvious permanent mental impairment and those in whom congenital mental deficiency is evident and forms the basis of the acute symptoms. In the matter of causation Dr. Hughes has found defective heredity in 71·4 per cent. of the direct admissions, a family history of insanity in 28 per cent., and of alcoholism in 13 per cent. Among other causes bodily disorders of various kinds were found to be present in a majority of the cases admitted and were regarded as having a direct influence upon the mental condition. It is very wisely pointed out that "such evidence proves the necessity for submitting every case to a thorough physical, as well as a mental examination ..... in order that suitable treatment of the physical ailment may be undertaken and every opportunity of complete recovery afforded. The moral effect of this system is also of great benefit, as the patients at once recognise that they are not merely 'put away,' but that they are regarded as being seriously ill and therefore sent to receive medical treatment." During the year 66 deaths occurred, and except in three of these cases post-mortem examinations were held.

Kingseat Asylum and Mental Hospital (Annual Report for the Year 1910).—The total number under treatment during the year 1910 was 563. There were discharged 77 persons, of whom 50 were discharged recovered. The admissions numbered 112, and of these 91 were certified as insane for the first time. There were 41 deaths, giving a rate of 9·2 per cent. on the average number resident, and 7·2 per cent. on the total number under treatment. Dr. H. de Maine Alexander, the medical superintendent, points out that "there are few mental affections which are not accompanied by well-defined physical symptoms. In a great many cases the insanity is entirely secondary to some physical disorder, which is really at the bottom of the mental trouble, and whose presence is very often not suspected on account of the mental symptoms filling the picture with their well-known obtrusiveness." Dr. Alexander also notes that in spite of the large amount of liberty extended to the patients and the opportunities afforded by the villa system there was no "escape" during the year. We entirely agree with him that the less restrictions there are about a mental hospital the better, and that the more it resembles a place of detention the more irritating it is likely to prove to the patients.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEETING OF COUNCIL.

A QUARTERLY meeting of the Council was held on July 13th, Sir HENRY BUTLIN, the President, being in the chair.

The PRESIDENT reported the re-election of Mr. C. T. Dent and Mr. G. H. Makins as members of Council, and they were introduced, made declarations in the terms of the oath prescribed by the Charter of 1800, and took their seats in the Council.

The Council congratulated the President on having received the honour of a baronetcy and Sir Anthony Bowlby on being knighted on the occasion of His Majesty's Coronation.

The names of two Members of the College which had previously been removed from the Medical Register were removed from the roll of Members.

Mr. J. Ernest Lane and Mr. Louis Albert Dunn were elected members of the Board of Examiners in Dental Surgery in the vacancies occasioned by the retirement of Sir Frederic S. Eve and Mr. Dent.

The following professors and lecturers were then appointed:—Sir Henry Butlin, two Hunterian lectures on "Cancer." Professor Arthur Keith, six Hunterian lectures on "The Contents of the Museum." Major Herbert C. French, R.A.M.C., two Hunterian lectures on "Syphilis." Mr. R. H. Paramore, one Hunterian lecture on the "Intra-abdominal Pelvic Pressure in Man." Mr. W. Girling Ball, one Hunterian lecture on "Acute Infective Processes due to the Streptococcus, with Special Reference to the Value of Vaccines and Serums in Treatment." Dr. J. W. H. Eyre, one Hunterian lecture on "The Pathology and Diagnosis of Tuberculosis of the Conjunctiva." Mr. H. T. Gray, one Arris and Gale lecture on "The Mechanism and Treatment of Shock." Dr. L. G. Parsons, one Arris and Gale lecture on "The Mechanism and Treatment of Shock." Professor Edward Fawcett, one Arris and Gale lecture on "The Development of the Human Chondro-cranium and Various Cranial Bones." Mr. S. G. Shattock, six Erasmus Wilson lectures on "Advanced Surgical Pathology." Professor Arthur Keith was appointed Arnott Demonstrator.

Sir Henry Butlin was re-elected President, and Mr. C. W. Mansell Moullin and Mr. C. T. Dent were appointed Vice-Presidents.

The next ordinary meeting of the Council will be held on Thursday, July 27th.

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

The Borough of Leicester.—The estimated population of this town for the middle of 1910 was 248,374, whereas the census enumeration amounted to only 227,242. In 1801 the population was 17,005. The birth-rate is steadily diminishing, and fortunately there is almost a corresponding decrease in the death-rate. The infantile mortality, too, is declining, and in 1910 it was only 126·4 per 1000 births. There was no case of small-pox during the year under review, and Dr. C. Killick Millard, in referring to the outbreak of this disease which occurred in London in the early part of 1911, expresses the opinion that had the first case never been vaccinated she would probably have had a more severe, and therefore recognisable, attack.[1] He thinks, too, that it is no longer legitimate to promote compulsory vaccination on the ground that unvaccinated persons are a danger to the community. Rather Dr. Millard appears to consider that it is the once vaccinated who are a danger to the community, inasmuch as modified cases of the disease are difficult to recognise. It must, however, be borne in mind that equally mild cases are sometimes to be observed amongst the unvaccinated, more especially when a mild type of the disease is prevailing. Dr. Millard has, however, no doubt as to the fact that recently vaccinated persons are, for all practical purposes, absolutely proof against small-pox, no matter how intimately they may be brought into contact with the disease. No indication is given as to what is meant by the word "recently," but the German experience teaches us that relatively remote vaccination is proof against the disease. With respect to enteric fever, a chart is furnished showing the fall which took place in the death-rate from this disease between 1898 and 1902, during which time over 5000 pail-closets were converted into water-closets. There was certainly an association in point of time between the two events, but it is doubtful how far they are to be regarded as causally related. There was also a marked fall between 1888 and 1892. As the medical officer of health observes, other factors were operating. However, the evidence of other towns must also be considered, and these data taken together render it probable that part of the fall may have been due to the substitution of water-closets for pails. There is, too, the fact that in Leicester a marked decline in diarrhœa and enteritis mortality took place between 1898 and 1902. Beds have been reserved since 1902 at the borough isolation hospital for the open-air treatment of phthisis, there being now 30 beds thus available. During 1910 there were 119 patients admitted, the average stay being 54·5 days. As regards results Dr. Millard's experience is that of most others who have made similar studies. The immediate results are highly satisfactory. Improved general health and appetite, increased weight and improved appearance; cough, expectoration, night sweats, and pyrexia diminish or disappear; and the physical signs improve. The other side of the picture is seen in the after-results. There is, however,

[1] Dr. Millard deals with this point in a letter in the present issue of THE LANCET (p. 252).

the educational value of the treatment to be considered. Dr. Millard is not prepared to give statistics, although it would seem that, under all the circumstances, they might be obtained as regards the discharged patients of each year. He adds, however, and he has clearly carefully weighed his words in relation to this very serious and responsible question, "I will merely say that inquiries made, say, a twelvemonth after patients have left the sanatorium, show that in more than half the cases treated the disease is recrudescing and the patient losing ground, whilst in some cases the patient will be dead or in a hopeless condition. Inquiries made two years after discharge show a still larger proportion in which the disease is recrudescing, whilst the number who have died will have increased, and so on as time advances." A large proportion of the cases are, he observes, lost sight of. This is a depressing conclusion, but it is, we are afraid, a true one as regards cases which are not carefully selected. The real point is, How far, if at all, are the lives of the patients prolonged and what is the minimum prolongation of life which, in the opinion of reasonable men, will justify the expenditure? Would longer treatment lead to better results and would it be wise to repeat the treatment each winter for a time, to approximate the condition of the poor to that of the rich who winter by winter seek the high altitudes of the Engadine? Dr. Millard is now considering the question of the establishment of a tuberculous dispensary where *inter alia* tuberculin could be employed. There is a milk depôt at Leicester where in place of "humanised" milk as usually supplied at depôts dried milk has been substituted, and this with what are regarded as such eminently satisfactory results that it is estimated that during the current year the receipts will actually equal the expenditure. It has not been found that any untoward results, such as infantile scurvy, accrue from the use of dried milk, which is becoming very popular both with the mothers and the medical practitioners in Leicester. This milk is prepared by being passed over highly heated iron rollers, the milk solidifying in the form of a thin blanket-like veil which is easily pulverised and which keeps readily. In an annotation in THE LANCET of July 8th, p. 110, we referred to the treatment at Leicester of scarlet fever and diphtheria during 1910.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns 8102 births and 3650 deaths were registered during the week ending July 15th. The revised estimate of the population of these towns in the middle of this year is 16,157,797 persons. The annual rate of mortality in these towns, calculated on this revised estimate, which had been equal to 11·3, 11·7, and 12·0 per 1000 in the three preceding weeks, declined again to 11·8 in the week under notice. During last quarter the annual death-rate in these towns averaged 13·8 per 1000, and in London during the same period the mean annual death-rate did not exceed 13·2 per 1000. The recorded annual death-rates in the 77 towns during last week ranged from 3·8 in York, 5·5 in Hornsey, 6·0 in Willesden, and 6·2 in Walthamstow, to 18·7 in Bury, 19·3 in Sunderland, 19·5 in Plymouth, and 19·6 in West Hartlepool. The 3650 deaths from all causes in the 77 towns last week showed a decline of 65 from the number in the previous week, and included 324 which were referred to the principal epidemic diseases, against 268 and 284 in the two preceding weeks. Of these 324 deaths, 136 resulted from infantile diarrhœa, 68 from measles, 45 from diphtheria, 43 from whooping-cough, 19 from scarlet fever, 12 from enteric fever, and 1 from small-pox. The mean annual death-rate from these epidemic diseases was equal to 1·0 per 1000, against 0·9 in each of the three preceding weeks. The deaths of infants under two years of age attributed to diarrhœal diseases in the 77 towns, which had been 70 and 87 in the two previous weeks, further rose last week to 136, and caused the highest annual rates, 1·3 in Liverpool and in Merthyr Tydfil, 1·5 in Bootle, and 1·7 in Southampton and in Rhondda. The 68 fatal cases of measles showed a further decline from the numbers in the 18 preceding weeks; they showed the largest proportional excess in Plymouth, Great Yarmouth, and Wolverhampton. The deaths referred to diphtheria, which had been 21, 35, and 36 in the three preceding weeks, further rose last week to 45, and included 14 in London and its suburban districts, 7 in Leeds, and 4 in Gateshead. The 43 fatal cases of whooping-cough showed a further decline from the numbers in recent weeks; 10 occurred in London and its suburban districts, and 3 in Manchester. The 19 deaths from scarlet fever, including 3 in London and 2 each in Birmingham and Sheffield, corresponded with the number in the previous week. The deaths referred to enteric fever, which had been 8 in each of the four preceding weeks, rose last week to 12. The fatal case of small-pox was registered in Birmingham. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had steadily increased from 982 to 1264 in the 13 preceding weeks, had further risen to 1345 on Saturday last; 204 new cases of this disease were admitted to these hospitals during the week under notice, against 163 and 191 in the two previous weeks. These hospitals also contained, at the end of last week, 804 cases of diphtheria, 397 of measles, 289 of whooping-cough, and 38 of enteric fever, but not one of small-pox. The 983 deaths from all causes in London last week exceeded the low number in the previous week by but 29, and included 119 which were referred to diseases of the respiratory system, against 117 and 102 in the two previous weeks. The deaths attributed to different forms of violence in the 77 towns, which had been 169 and 155 in the two preceding weeks, were last week 194, and 351 inquest cases were registered. The causes of 27, or 0·7 per cent., of the deaths registered in the 77 towns during the week under notice were not certified either by a registered medical practitioner or by a coroner. All the causes of death during last week were duly certified in Manchester, Sheffield, Leeds, Bristol, West Ham, Hull, Newcastle-on-Tyne, and in 55 other smaller towns; the 27 uncertified causes of death in the 77 towns last week included 7 in Liverpool, 5 in Birmingham, and 3 in Stoke-on-Trent.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns, having an estimated population of 1,710,291 persons in the middle of this year, 820 births and 488 deaths were registered during the week ending July 15th. The annual rate of mortality in these towns, which had been equal to 13·3, 14·2, and 14·6 per 1000 in the three preceding weeks, further rose to 14·9 in the week under notice. During last quarter the annual death-rate in these towns averaged 16·7 per 1000 of the revised estimate of their population, and exceeded by 2·9 the revised mean rate during the same period in the 77 large English towns. The annual death-rate during last week in the eight Scotch towns ranged from 9·1 and 11·7 in Leith and Dundee to 17·3 in Greenock and 18·9 in Edinburgh. The 488 deaths from all causes in the eight towns last week showed a further increase of 11 upon the numbers in recent weeks, and included 57 which were referred to the principal epidemic diseases, against 63 and 49 in the two previous weeks; of these 57 deaths, 23 resulted from whooping-cough, 18 from infantile diarrhœa, 6 from measles, 5 from scarlet fever, 4 from diphtheria, and 1 from enteric fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases in the eight towns last week was equal to 1·7 per 1000; the mean rate last week from the same diseases in the 77 English towns did not exceed 1·0 per 1000. The fatal cases of whooping-cough, in the eight Scotch towns, which had steadily declined in the six preceding weeks from 43 to 12, rose again last week to 23, and included 12 in Glasgow and 8 in Edinburgh. The 18 deaths attributed to infantile diarrhœa showed an increase of 4 upon the number in the previous week; 7 occurred in Glasgow, 3 in Edinburgh, and 2 each in Dundee, Greenock, and Perth. The 6 fatal cases of measles, of which 5 were returned in Glasgow, were fewer by 8 than the number in the previous week. The 5 deaths from scarlet fever showed, however, an increase upon recent weekly numbers, and included 2 both in Edinburgh and in Aberdeen. Three of the 4 fatal cases of diphtheria and the death from enteric fever were recorded in Glasgow. The deaths referred to diseases of the respiratory system in the eight towns, which had been 48 and 56 in the two previous weeks, declined to 47 in the week under notice, and were 2 below the number in the corresponding week of last year. Of the 488 deaths

from all causes in the eight towns last week, 148, or 30 per cent., were recorded in public institutions, and 28 were attributed to different forms of violence. The causes of 22, or 4·5 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 77 English towns the proportion of uncertified causes of death during the week did not exceed 0·7 per cent.

HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,149,495 persons in the middle of this year, 581 births and 369 deaths were registered during the week ending July 15th. The annual rate of mortality in these towns, which had been equal to 17·0 and 14·2 per 1000 in the two preceding weeks, rose again to 16·7 in the week under notice. During last quarter the annual death-rate in these towns averaged 17·9 per 1000; the mean rate during the same period in the 77 English towns did not exceed 13·8, and in the eight principal Scotch towns was 16·7 per 1000. The annual death-rate during the week under notice in the 22 Irish towns was equal to 20·9 in Dublin (against 11·3 in London), 16·6 in Belfast, 11·6 in Cork, 19·2 in Londonderry, 10·9 in Limerick, and 5·7 in Waterford; in the 16 smallest of these Irish towns the mean annual death-rate last week did not exceed 12·1 per 1000. The 369 deaths from all causes in the 22 towns last week showed an increase of 57 upon the low number in the previous week, and included 35 which were referred to the principal epidemic diseases, against 21 and 22 in the two previous weeks; these 35 deaths were equal to an annual rate of 1·6 per 1000, exceeding the mean rate from the same diseases in the 77 English towns by 0·6. These 35 deaths in the Irish towns last week from the principal epidemic diseases included 15 from infantile diarrhœa, 7 from measles, 4 from scarlet fever, 4 from diphtheria, 3 from enteric fever, and 2 from whooping-cough, but not one from small-pox. The 15 deaths from infantile diarrhœa exceeded by 7 the number in the previous week, and included 5 in Dublin and 9 in Belfast. The fatal cases of measles, which had been 9 and 6 in the two previous weeks, were 7 last week, all of which occurred in Dublin. The 3 deaths referred to enteric fever, 3 of the 4 fatal cases of scarlet fever, and 3 of the 4 deaths from diphtheria, were recorded in Dublin. One death from scarlet fever occurred in Belfast, and one from diphtheria in Dundalk. The deaths referred to diseases of the respiratory system in the 22 towns, which had been 54 and 46 in the two previous weeks, rose again to 52 last week. Of the 369 deaths from all causes in the 22 towns last week, 132, or 36 per cent., were recorded in public institutions, and 12 were referred to different forms of violence. The causes of 12, or 3·3 per cent., of the deaths registered in the 22 towns last week were not certified either by a registered medical practitioner or by a coroner after inquest; the proportion of uncertified causes of death during the week under notice did not exceed 0·7 per cent. in the 77 large English towns, and was equal to 4·5 per cent. in the eight principal Scotch towns.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Fleet-Surgeons: F. J. A. Dalton to the *Prince George*, on recommissioning; Edward C. Cridland to the *Illustrious*, on recommissioning. Staff-Surgeons: C. C. Macmillan, D.S.O., to the *Gibraltar* and to the *Pyramus*, on recommissioning; Godfrey Taylor to the *Naiad*; C. E. C. Stanford to the *New Zealand*, on commissioning; J. H. Lightfoot to the *Crescent* and to the *Psyche* on recommissioning; G. E. Duncan to the *Crescent* and to the *Pioneer*, on recommissioning; Thomas H. Vickers to the *King Edward VII.*, additional, on transfer of flag; C. B. Fairbank to the *Flora*, on recommissioning; and R. Kennedy to the *Sphinx*. Surgeon: J. S. Orwin to the *Clio*.

ROYAL ARMY MEDICAL CORPS.

Colonel L. E. Anderson, principal medical officer of the Allahabad Brigade, has been appointed Principal Medical Officer of the Bareilly, Garhwal, and Dera Dun Brigades in succession to Colonel M. Kerin, C.B. Lieutenant-Colonel R. W. Wright, at present serving at Shoeburyness, has been placed under orders for a tour of duty in the Northern Army, India. Lieutenant-Colonel W. W. Pike, D.S.O., from the military hospital at Tidworth Park, Salisbury Plain, has taken up duty as Senior Medical Officer at Cairo. Lieutenant-Colonel H. L. E. White has arrived home on leave from Malta. Lieutenant-Colonel M. O'Halloran has been appointed in charge of the Military Hospital at Canterbury. Lieutenant-Colonel J. H. Daly, at present serving at Limerick, has been detailed by the War Officer for a tour of duty in South China. Lieutenant-Colonel L. T. M. Nash, commanding the Station Hospital at Karachi, has been granted six months' leave of absence home from India. Lieutenant-Colonel C. T. Blackwell has taken up duty at Rangoon in command of the Station Hospital. Major E. C. Anderson, D.S.O., has been transferred from Kuldanna to the Fourth (Quetta) Division for the temporary command of the Station Hospital at Karachi. Major B. Watts, at present serving at Campbellpore, has been granted three and a half months' general leave. Major H. B. G. Walton has been appointed Specialist in Advanced Operative Surgery to the Seventh (Meerut) Division of the Southern Army. Major G. St.C. Thom has been granted one year's extension of his Indian tour of service by H.E. the Commander-in-Chief. Major A. W. Bewley, from the Station Hospital at Meerut Cantonment, has taken up duty as Senior Medical Officer at Landour. Major G. J. A. Ormsby has been transferred from Fyzabad to Dinapore. Major J. F. Burke, from Falmouth, has been appointed to the Medical Charge of the troops at Lancaster. Major J. McD. McCarthy, from Chester, on arrival in India has been appointed for duty at Multan. Major C. F. Wanhill, assistant professor of military hygiene at the Royal Army Medical College, London, has been placed under orders for a tour of service in India. Major C. W. R. Healey has arrived home on leave of absence from Nasirabad. Captain J. F. Whelan from Manchester has taken up duty at Nowgong. Captain A. B. Smallman has been transferred from the military hospital at Colchester to Woolwich. Captain W. McConaghy from Birmingham has been appointed to Tidworth Park, Salisbury Plain. Captain M. Dunbar Walker has been appointed Specialist in Physical Training at the Royal Army Medical College, London. Captain F. J. Stuart has been appointed Specialist in the Prevention of Disease with charge of the Brigade Research Laboratory at Fyzabad. Captain C. J. Coppinger has taken up duty in the Irish Command. The following officers have been detailed by the War Office to proceed abroad for duty with the Southern Army in India: Captains J. Tobin, A. R. Greenwood, P. C. Douglass, J. L. Jones, H. A. Bransbury, and A. W. Sampey. Lieutenant A. Shepherd from Agra has joined for duty at Landour. Lieutenant D. S. Buist, from the Royal Victoria Hospital at Netley, has been appointed to the Station Hospital at Quetta.

INDIAN MEDICAL SERVICE.

The King has approved of the following promotions:—Lieutenant-Colonel Harold Hendley to be Colonel (dated April 7th, 1911). Lieutenant-Colonel Robert Bradley Roe to be Colonel (dated April 30th, 1911). Colonel Roe's tenure of appointment will reckon from May 6th, 1911.

The promotion of Major T. S. Novis is antedated from July 27th, 1910, to Jan. 28th, 1910.

The King has approved of the retirement of Colonel William O'Hara (dated June 7th, 1911), and Lieutenant-Colonel John William Rogers (dated July 5th, 1911).

Colonel H. Hendley has been appointed Principal Medical Officer of the Sirhind and Jullundur Brigades, Third (Lahore) Division, in succession to Colonel A. M. Cofts, appointed Principal Medical Officer of the Second (Rawal Pindi) Division. H.E. the Governor of Bombay in Council has appointed Lieutenant-Colonel J. G. Hojel to officiate as physician to St. George's Hospital at Bombay during the absence on leave of Lieutenant-Colonel M. A. T. Collie. Lieutenant-Colonel W. Ronaldson Clarke has taken up duty at Lahore Medical College as Civil Surgeon and Professor of Forensic Medicine in succession to Colonel Hendley. Lieutenant-Colonel A. H. Nott, Bengal Presidency, has arrived home on leave of absence from India. Major A. F. Stevens, civil surgeon of Murshidabad, has been appointed Civil Surgeon at Hazaribagh. Major H. F. Knapton has been granted 35 days' privilege leave. Major R. H. Maddox has

been selected to succeed Captain E. P. O'Connor as Civil Surgeon at Gaya. Major B. R. Chatterton, civil surgeon at Muzaffarpur, has been granted seven months and nine days' leave of absence home from India. Major J. A. Black has been confirmed in the appointment of Chemical Examiner, Punjab, and Professor of Chemistry in the Medical College, Lahore, by the Home Department, Government of India. Major C. A. Lane, on return from leave, has been appointed Civil Surgeon at Murshidabad, in succession to Major J. G. P. Murray. Captain W. G. Hamilton has been succeeded as Superintendent of the Central Jail at Midnapore by Captain F. H. Salisbury. Captain H. M. Inman has been appointed to officiate as Civil Surgeon at Jacobabad. Captain S. J. Bathena has taken up duty under the Jail Department in the Bombay Presidency. Captain N. S. Simpson has been selected to succeed Captain L. Reynolds as Medical Officer of the Lawrence Military Asylum, Sanaway, Punjab. Captain E. Bisset has been placed on plague prevention duty in the Meerut District. Captain E. P. Wernicke has arrived home on leave of absence from India.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Major Edward C. Thompson relinquishes his commission (dated July 15th, 1911).

TERRITORIAL FORCE.

Royal Army Medical Corps.

Yorkshire Mounted Brigade Field Ambulance, Royal Army Medical Corps: Thomas Edmund Lister to be Lieutenant (dated June 1st, 1911).

NAVAL MEDICAL SUPPLEMENTAL FUND.

At the quarterly meeting of the directors of the Naval Medical Supplemental Fund, held on July 11th, Inspector-General W. H. Lloyd, R.N., in the chair, the sum of £35 was distributed among the several applicants.

UNITED SERVICES MEDICAL SOCIETY.

The annual general meeting of this society was held at the Royal Army Medical College under the chairmanship of Colonel Sir David Bruce, C.B., F.R.S. The secretaries reported that the balance credit of the society had increased by £5, but that owing to increased expenditure on the publication of the Transactions it would be necessary to obtain more members to keep the society on a sound footing. During the past year there had been nine meetings, at which 17 papers were read, and the policy of the secretaries had been to emphasise the military character of the society, since it was felt that there was already an abundance of purely medical societies. The following officers were elected:—President: Major E. B. Waggett, R.A.M.C.(T.). Treasurer: Major S. Lyle Cummins, R.A.M.C. Members of Council: Staff-Surgeon Dudding, R.N., Major C. E. Pollock, R.A.M.C., Lieutenant-Colonel P. J. Freyer, I.M.S. (R.), and Lieutenant-Colonel E. Lloyd Williams, R.A.M.C. (T.). On the motion of Lieutenant-Colonel Sir William Leishman, R.A.M.C., a hearty vote of thanks was passed to the retiring officers, especially the President, Colonel Sir David Bruce, and the treasurer, Lieutenant-Colonel J. B. Wilson, R.A.M.C. Colonel Sir David Bruce, in reply, referred to the work on preventive medicine as the most important part of the duties of service medical officers. As instances of the value of such work he pointed to the almost complete abolition of Mediterranean fever from the garrison at Malta; this represented a saving which, capitalised, amounted to a gain of something like 1½ millions sterling for an expenditure of about £5000. The work on enteric fever had resulted in a reduction of the incidence in India from 15·6 per 1000 five years ago to a present rate of 4·6 per 1000. This was due to inoculation, segregation of carriers, and improved methods of disposal of excreta, all of which had been indicated largely as a result of researches by medical officers. The saving of lives alone in India must represent a capitalised value of more than 1½ millions. Such economies as these could be obtained in no other sphere of work, and he urged medical officers to devote more and more of their time to prevention and research. At the present time the problem of the prevention of malaria in our tropical garrisons was a subject calling urgently for solution.

Correspondence.

"Audi alteram partem."

THE NATIONAL INSURANCE BILL.

To the Editor of THE LANCET.

SIR,—What is adequate remuneration? The question will have to be asked, and its reply will contain the future of the profession, which is a matter of more vital moment to the nation than the fate of any Bill, howsoever beneficent, and which should be the first care of the State. Much irrelevant discussion of impossible terms might have been avoided had that inevitable question been asked in legitimate course of our accredited authorities. Would the Church or the Law ever have been offered the slur of a commandeering of the services of their irresponsible units at a wage not previously discussed with their constituted governing bodies? In principle the State cannot negotiate matters of professional and public interest with individuals or on the basis of individual circumstances. Any attempt, both unbusinesslike and, with all reservation for the best intentions, inequitable, to enter into any such irregular conversations should not have been entertained, but referred to the proper quarter. Much credit and much time have been lost. At any rate, a short respite has been gained—to ponder upon the significance of that official manœuvre and over the error of our tactics in meeting it.

Is the future health advantage of the masses, for which hitherto we alone have toiled and paid, to be constructed upon the basis of our past charities to them and to the State? Where does our own future come in, which should be the State's first concern? And what, too, of the repayment of those long arrears, when we stood vicariously for it *in loco parentis* towards them, and in a unique position among all professions, as contributing to the State unlimited treasure in lives, in efficient health, and in productive labour? Shall we put our own seal to a deed of perpetual sweating, presented to us ingeniously in belated acknowledgment of a long course of free giving? The State has forgotten, it could hardly repudiate, its obligation; and the rank and file of the profession are being mesmerised into forgetfulness over the Chinese puzzles which have been cast at them. Meanwhile we are still waiting for the main answer from the appointed guardians of our status as a profession.

What is the irreducible minimum compatible with the claims of our great past and with the greater claims of our future? It belongs to the honour of the profession not to recognise any of the baser coinage. The Westminster Division of the British Medical Association was the first to assert that essential principle in a resolution passed two months ago as the only safeguard against the official debasement threatening an order which had hitherto been free to pity rather than to resent. In practical terms of the situation, free scope should be afforded to the discussion of figures with any Local Health Committee in those districts which may opt for a basis of "remuneration for services rendered"; the profession cannot be committed by any individual negotiations special to localities. But in others, where it would become irretrievably committed, on the basis of a *capitation fee*, under a direct compact with the State, the irreducible minimum should be half-a-guinea, with faculty to claim more, if justifiable, but under no condition less. That resolution, which has been adopted by other divisions, stands, and any settlement on meaner terms could not receive the sanction of a unanimous profession.

I am, Sir, yours faithfully,

WILLIAM EWART,

Formerly President of the Westminster Division of the British Medical Association.

The Athenæum, July 13th, 1911.

To the Editor of THE LANCET.

SIR,—I desire to bring to the notice of the profession the paramount importance of the *Local Medical Committees*. Their importance unfortunately seems to be improperly appreciated. Thus with regard to Clause 14, the amendment agreed upon by the British Medical Association reads as follows:—

Every approved society and Local Health Committee shall ..... make arrangements with duly qualified medical practitioners in accordance with regulations made by the Insurance Commissioners.

What an immense difference it would have made to the profession had the clause read as follows:—

Every approved society and Local Health Committee shall ..... make arrangements with duly qualified medical practitioners *through the Local Medical Committees in each local area.*

As the clause stands (as agreed to by ourselves) it provides that *local individual competition* (cutting remuneration down to the lowest possible point) will take place in every local area, whilst our liberty of action is given into the hands of the Insurance Commissioners.

Not content with this restriction of our freedom, and apparently without trying to obtain *the power of bargaining* between the Local Health Committees and the Local Medical Committees, the Chancellor has been permitted to frame the following, so that where individual competition fails (from the loyalty of medical men to each other), then the introduction of "whole-timers" may be brought into local areas in order to cut down remuneration or resistance. Hence the following:—

If the Insurance Commissioners are satisfied that the practitioners ..... are not such as to secure an adequate medical service in any area, they may dispense with ..... the adoption of such system ..... and authorise the (health) committee to make ..... other arrangements.

Thus whilst the Bill makes no mistake in providing for adequate medical service, the question of adequate medical remuneration is entirely ignored. In other words, the astute Chancellor gets his Bill, and we are to fight locally (as individuals, not as a local executive) for adequate remuneration. But as the Local Health Committees have to pay half of any extra remuneration (above the 6*s.* capitation fee on which the Bill was founded) out of the already overburdened local rates, it naturally follows that the competition of "weaker professional brethren" or of "whole-time" men will be exploited to the utmost.

I am glad to say that at my suggestion the Newcastle-on-Tyne and Gateshead executive have adopted the following amendments as their policy with regard to this point in the Bill. And as these amendments would put us into a position to resist local sweating and inadequate remuneration, and as they would give us the power of bargaining locally, I strongly commend them to the notice of every practitioner and of every branch of the Association. They read as follows:—

1 *Clause 14.*—Every Local Health Committee shall, for the purpose of administering medical benefits, make arrangements with registered medical practitioners, *on terms approved by the Local Medical Committee*, for insured persons entitled to such benefit.

2. *Clause 44.*—The Local Medical Committee shall be elected by the registered medical practitioners practising in each local area, and shall arrange, in conjunction with the Local Health Committee, all matters affecting the arrangements with registered medical practitioners to give attendance and treatment to the insured.

Given the £2 wage limit the above amendments would tend to meet the just and reasonable requirements of the profession. Without them there will, I fear, be inadequate remuneration, and little security or peace in the local areas.

I am, Sir, yours faithfully,

T. M. ALLISON, M.D. Durh.

Newcastle-on-Tyne, July 15th, 1911.

To the Editor of THE LANCET.

SIR,—Will you permit me to urge all medical men who have not yet signed the declaration sent out by the Medical Association to do so without delay? Letters have appeared stating that some medical men do not care to sign until they know the conditions under which they serve, but, Sir, then it will be too late. What we want is a united profession to make *our own* conditions. If the profession does not stand solid now they will never have another chance of making a successful stand against the evils of club practice. We have to consider not only the financial side but the standing of the profession in the eyes of the public.

I am, Sir, yours faithfully,

Isle of Wight, July 14th, 1911. C. G. BRODIE, F.R.C.S.Eng.

THE POSITION OF THE PRESENT REFORM MOVEMENT IN ANÆSTHETICS.

To the Editor of THE LANCET.

SIR,—Any statement by Dr. J. F. W. Silk on the proposed legislation with regard to anæsthetics is well worthy of consideration. But it is generally acknowledged that the public stand in need of some protection. Vendors of poisons are required to be qualified for their position; how much more should the administrators of anæsthetics be highly trained? Sir Frederic Hewitt's scheme appears to be a very moderate one, and his persistent advocacy has made it acceptable to large numbers of the profession. Any seeming lack of enthusiasm is, in my opinion, due to the fact that the passing of the measure is a mere matter of time, and is in no sense due to indifference to the question.

I am, Sir, yours faithfully,

Dublin, July 15th, 1911. GEORGE FOY.

To the Editor of THE LANCET.

SIR,—It is satisfactory to find from Sir Frederic Hewitt's courteous reply to my letter that there are so many points on which we fully agree. He puts my first point even a little more strongly than I did—viz., that there are far more anæsthetic fatalities under registered than under unregistered administrators, and that there would be very little gained by the passage of an Act which would protect the public against the latter class of practitioners only. Of course, I also agree that if there is to be legislation on the subject at all it should commence by rendering it illegal for unqualified persons to administer such potent drugs except under the immediate supervision of a qualified medical man.

There is a third point on which I know from the memorandum published in Sir Frederic Hewitt's paper in THE LANCET that we are agreed, and that is in lamenting that there are at present no reliable statistics as to the proportion of deaths under anæsthetics to the number of administrations thereof, either in some of our large hospitals or in private practice, but in this matter I understand that a change for the better has already commenced in the hospitals.

We come next to the two matters on which I am obliged, with much regret, to differ somewhat from Sir Frederic Hewitt. When I was investigating this matter some three years ago for one of the medical journals, what I may call the personal factor was not neglected. What I found was that at the hospital where fatalities had been numerous, recently qualified students, who had mostly attained the rank of house physicians and house surgeons, were called upon, in the absence of the appointed anæsthetists, to act as administrators, while at another hospital some of the same class of recently qualified men were appointed assistant anæsthetists. The difference did not seem to me sufficient to account in any way for the increased mortality, and I hope Sir Frederic Hewitt does not mean us to apply to the former class the teaching of science with regard to properly educated and qualified persons who "use these drugs in such a way as to transgress the laws which are now known to be essential for safe anæsthetisation"? With regard to what Sir Frederic Hewitt is pleased to call the methylated chloroform *bogey*, he will find, I believe, that its influence has spread not only over the United Kingdom, but to our colonies. Last year I paid a flying visit to Sydney and New South Wales, and found that both in the fine up-to-date Sydney Hospital and also in a small private hospital 150 miles up the country in the Blue Mountains only Burroughs and Wellcome's pure chloroform was used.

Sir Frederic Hewitt has, of course, before adopting methylated chloroform in his practice, well considered the arguments against it, but I cannot tell whether his attention has been called to some experiments made by Dr. du Bois-Reymond in conjunction with a French chemist, M. Pictet. Pictet believed that the only way to get a perfectly pure chloroform was by repeated freezing of ordinary chloroform. The mother liquid from which the chloroform has been frozen out resembles chloroform physically, but contains residues which, according to du Bois-Reymond, differ considerably physiologically and have a deleterious effect upon the organism. As to what these impurities or residues consist of, nothing appears to be known, but it is possible that they are composed of bodies possessing a profoundly depressant action on the heart. Du Bois-Reymond adds that the amount of impurities is slight, but though minute, they act strongly when dissolved in chloroform and their presence is enough seriously to affect the person or animal inhaling them. In the same annotation in the *British Medical Journal* (Feb. 15th, 1908, p. 405), in which these experiments are referred to, it is stated that Dudley Buxton has pointed out that methylated spirit is very difficult to purify, and is liable to contain by-products such as chlorinated oil, &c.

This question of the danger of using methylated chloroform was first raised, it must be remembered, in the coroner's court, and I hope Sir Frederic Hewitt will agree with me in thinking that neither the coroner's court nor a committee of the House of Commons is the most suitable place for such a discussion. Let both sides, I would suggest, be heard before a section of the Royal Society of Medicine, or let the General Medical Council give a definite pronouncement on the subject, and the bogey, if it be found to be one, will be set at rest for ever.

I am, Sir, yours faithfully,

July 15th, 1911. H. NELSON HARDY.

VACCINATION IN REGARD TO LIFE ASSURANCE.

To the Editor of THE LANCET.

SIR,—In THE LANCET of June 17th Mr. W. H. Jalland has a thoughtful article under the above title which I have read with interest. As he refers to the remarkable experience of Leicester in regard to small-pox, for which town I have been medical officer of health for ten years, I should like to make a few observations. Mr. Jalland has not got the facts as to Leicester quite correctly. He speaks as if there had only been two epidemics, those of 1892 and 1903, since compulsory vaccination was abandoned 28 years ago, whereas there was a third epidemic in 1904 with a further 321 cases. In addition to these epidemics there have been repeated minor outbreaks due to importations. Thus in 1902 there were seven separate outbreaks, resulting in 18 cases. It is very evident, therefore, that the Leicester experiment has been very thoroughly tested, and it is a little surprising that the lessons to be learnt from it—so totally different from what was confidently predicted—have received so little attention. It cannot be denied that they have a most important bearing upon the subject Mr. Jalland discusses.

The real question at issue is briefly this:—It is obvious that infantile vaccination is falling more and more into disuse—Does this fact and the existence of an increasing proportion of unvaccinated persons in a community necessarily involve, *under present-day conditions in this country*, an increasing risk of small-pox mortality? The orthodox answer of the medical profession is, "Most certainly, yes." But the arguments upon which this answer is based are all of a more or less theoretical or indirect character, and I venture to submit that, convincing though they may seem *a priori*, they ought not to have the same weight attached to them as to the definite results of a crucial experiment, such as has been carried out in Leicester. We have in Leicester a large industrial town, with over 200,000 inhabitants, which has so completely set the vaccination laws at defiance that in the past 28 years, whilst there have been 155,880 births, only 19,562 vaccinations have been registered—i.e., 12·5 per cent. At the time of the last two epidemics the vast majority—say, 80 or 90 per cent.—of the school children in the town were unvaccinated, together with a large number of the young adults employed in the factories. Small-pox has been repeatedly introduced into the town. It has three times succeeded in establishing itself in epidemic form. In one epidemic as many as 50 cases occurred in one week, and as many as 150 in a period of four weeks. Yet the disease has never "caught on" amongst the unvaccinated section of the community, nor has it ever been necessary during my term of office to close a school on account of small-pox. Surely such an experience would be impossible if orthodox theories about the danger of the spread of small-pox amongst unvaccinated persons were correct.

Mr. Jalland refers to and quotes "missed" cases of small-pox as "an interesting point showing how epidemics may spread." This has been precisely our trouble in Leicester. It is the "missed" cases which have baffled us and done the mischief, just as was the case with the recent unfortunate outbreak in the Mile End Infirmary, where a "missed" case of small-pox in a child of 12 years, Annie L——, was treated for a fortnight in the general wards instead of being sent to the small-pox hospital, with the result that a serious outbreak occurred. But Mr. Jalland omits to state—probably he does not realise the importance of the point—that these "missed" cases, with all the mischief which results from them, are *essentially a product of vaccination*, for they occur far more frequently amongst persons who have been once vaccinated than amongst the unvaccinated; the explanation being, of course, that vaccination after it has ceased to protect against an attack of small-pox still has the power of modifying, and thereby masking, the disease. So much is this the case that small-pox in vaccinated subjects may easily baffle the most expert diagnostician, much more so the general practitioner. The child, Annie L——, referred to above, who caused the outbreak in the Mile End Infirmary, directly resulting in 30 cases with eight deaths, *was a vaccinated case*. Will anyone assert that it is probable the same unfortunate mistake would have been made if this child had been unvaccinated? Hitherto this characteristic of vaccination in modifying small-pox has only been looked at from the narrow point of view of the person attacked. We are only now beginning to consider that from the broad point of view of the prevention of disease by the modern methods of notification and isolation this characteristic, hitherto regarded as an advantage, *is really a most serious drawback*. I submit that the extent of this drawback is not yet fully appreciated. Mr. Jalland, in referring to the Leicester system, speaks as if "contacts" were still removed from their homes for purposes of quarantine. This was formerly practised, it is true, but has never been resorted to during my term of office. There is little occasion for it where contacts can be persuaded to be vaccinated promptly, or, even though they refuse, provided they are paid to stay at home and are visited daily. Nor is the Leicester system an expensive one, as is so often urged against it. On the contrary, I submit that it is *far cheaper* than a system of universal vaccination and revaccination (followed by a third vaccination of all males as in Germany) would be. Space forbids me to enter into this here, but I am quite prepared to justify my statement.

The Leicester experiment is about as conclusive as the experience of any one town can be. It has now lasted for a quarter of a century. It is confirmed by the more recent experience of the country generally, where an increasing neglect of vaccination has not been followed by any evidence of an increase of small-pox mortality. I have thought about this question for a good many years, and I may claim to have had some little experience of the subject, having been in the Birmingham epidemic of 1893–94 before I came to Leicester. One hesitates to speak out about such a burning question as vaccination, and one realises, of course, the great gravity of the issues at stake, but I wish to say frankly that in my judgment the only evidence that can reasonably be set against the evidence of Leicester is (1) the breakdown of the "Leicester system" in Leicester itself, or (2) its breakdown in some other town *where it has been fairly tried*. This evidence is not yet forthcoming, and until it is the experience of Leicester cannot be ignored. In conclusion, to prevent misunderstanding, let me say that no medical man who knows the subject believes more strongly than I do in the power of recent vaccination to confer temporary immunity against small-pox. I regard vaccination as the greatest triumph of the science of preventive inoculation, and I would never dream of attempting to fight small-pox as a medical officer of health without its aid. Moreover, if small-pox in any community once *really* got out of hand I would be prepared to advise without hesitation the immediate vaccination of the whole community; and if it were not for the unfortunate prejudice—engendered by the almost cruel and bigoted persecution of anti-vaccinators in the past—such a wholesale vaccination, as a *dernier ressort*, would be quite practicable. It was done in Glasgow not so many years ago. It would cut short any epidemic in three weeks. But I believe that the necessity for such a step would rarely, if ever, occur if the methods adopted in Leicester were fairly tried, and especially if it were freed from the very serious handicap, under which it at present suffers, of having amongst its population a large number of once vaccinated—i.e., partially vaccinated—persons. I believe that this country has now reached such a state of public health efficiency that it will be found to be possible to control small-pox satisfactorily (i.e., quite as well as has been possible in the past, when vaccination alone was depended upon) even though compulsory vaccination has become a thing of the past. There are, no doubt, weak spots here and there, but it must be our business to strengthen these. Of this I feel certain, and I believe many others are coming to think the same, that as time goes on we shall come

to depend more and more upon such measures as notification, isolation, and supervision of contacts, &c., rather than upon infantile vaccination of the general population. The future lies with the medical officer of health rather than with the public vaccinator.—I am, Sir, yours faithfully,

C. KILLICK MILLARD, M.D., D.Sc. Edin.,
Medical Officer of Health.

Town Hall, Leicester.

THE RESOLVING POWER OF THE MICROSCOPE.

To the Editor of THE LANCET.

SIR,—Mr. A. S. Percival questions the utility of continuing the discussion in THE LANCET of the accuracy of the formula relating to the resolving power of the microscope in view of the intricate nature of this subject, and I think he is right, since to arrive at a final solution it will be impossible to exclude lengthy mathematical arguments, which are not likely to appeal to many readers of THE LANCET. Under these circumstances I will endeavour to arrive at an acceptable solution of the question which has arisen through the medium of direct correspondence with Messrs. Percival and Whittaker. Perhaps we may in this way succeed in removing the existing difference of opinion, and in that case I would suggest that the result of our discussion may be communicated to the readers of THE LANCET.

In the meantime I will content myself with the statement of the following bare facts without reference to mathematical argument or to the diffraction theory: (1) The formula $d = \frac{\lambda}{a}$ is undoubtedly correct when we are concerned with the separation of the consecutive bars of a grating (indeed, it holds good when a telescope is brought to bear upon celestial objects presenting features of the nature of a grating, such as the canals of Mars); (2) similarly, the formula $d = 0{\cdot}61\frac{\lambda}{a}$ is correct when a telescope is employed to resolve the distance between two stars, as in the case of doubles. On the other hand, no serious student of optics will dispute the fundamental identity of the *modus operandi* of the telescope and the microscope. We need only remember that we have telescopes to view objects close to their objective, and again, that there are microscopes for viewing comparatively distant objects, and this suggests the possibility and necessity of dealing with the resolving power of these two instruments, and for that matter of all optical instruments, by adopting the same reasoning throughout.

In contrasting these two formulæ it behoves us, however, to bear in mind that it matters greatly whether the details which are to be resolved are of the nature of periodically recurrent structures, or whether they consist merely of two isolated elements. The formula quoted by us, viz., $d = \frac{\lambda}{a}$, applies to periodically recurrent features, such as occur very frequently in natural objects, for instance, butterfly's scales, diatoms, &c. The same formula applies, however, very approximately also to objects of any structural arrangement.

In conclusion, it may be useful to recall the well-known fact that the resolution of adjacent elemental features and the mere act of bringing them into view are by no means synonymous, for it is possible to bring into view extremely small granules or filaments, such as bacteria and their flagelle, whose dimensions may be much smaller than the limit of resolution of a grating. This result is solely a function of the defining qualities of the lenses, the sensibility of the retina of the eye, or the photographic plate, as the case may be, and, above all, of the contrast in the illumination of the small objects relatively to their surroundings. It is precisely this last-named artifice which is the underlying principle of the methods of dark-ground illumination and ultra-microscopic observation.

I am, Sir, yours faithfully,

July 5th, 1911. E. LEITZ.

To the Editor of THE LANCET.

SIR,—I am afraid that I have failed to make my point about the formula for resolution as clear as I should have done. The resolving power of a microscope means its power of resolving two adjacent points, and I gather from his letter that Mr. Leitz now admits that the formula $\frac{0{\cdot}61\lambda}{a}$ is correct when two points only are considered. But Mr. Leitz proceeds to say that if the details which are to be resolved are of the nature of periodically recurrent structures the formula $\frac{\lambda}{a}$ is applicable. This is practically the formula that is used to determine the wave length of light with a diffraction grating (it is well known that the number of lines in a grating affect only the purity of the spectrum), but it is not the correct formula for the resolving power of a microscope, which is, as Dr. Whittaker insists, obtained by introducing the constant 0·61. This is rendered necessary by the consideration of an important mathematical point that was brought out by Sir George Airy, Lord Rayleigh, and Abbé, but was omitted in the incomplete methods used by Drude and others.

The remark that has been applied to Abbé might perhaps be also applied to the other authors I have quoted—namely, that it is necessary to "assume a very high degree of physical and optical insight in his readers"; and that these papers "have in consequence been misunderstood and misinterpreted in all sorts of extraordinary ways by critics falling below the assumed standard of knowledge" (Spitta's Microscopy, p. 401). Without such knowledge it is useless to try to follow the reasoning that has led to the substitution of $\frac{0{\cdot}61\lambda}{a}$ for $\frac{\lambda}{a}$ in dealing with the resolving power of the microscope. I am, Sir, yours faithfully,

July 11th, 1911. A. S. PERCIVAL.

*** Mr. Leitz's letter, it will be seen, was sent to Mr. Percival for his consideration.—ED. L.

SALVARSAN ("606") AND MERCURY IN THE TREATMENT OF SYPHILIS.

To the Editor of THE LANCET.

SIR,—Salvarsan is now universally recognised as an important factor in the treatment of syphilis, and although it may not altogether supersede the older methods of treatment, it must be admitted that a welcome advance has been reached. The celerity with which buccal lesions yield to its administration is nothing short of a revelation. It is no uncommon thing for mucous patches of tonsils, lips, and tongue to disappear within a week under its action. Forty cases of syphilis have been treated by this agent within the last five months at the Liverpool Royal Infirmary (Department for Specific Diseases). The cases included the three stages of the disease, ranging from infections of from two months to 12 years. At first the salvarsan was administered intramuscularly into the upper and outer margin of the gluteus maximus, afterwards the intravenous method was employed. The median basilic was found to be the most convenient vein to convey the solution. As far as my experience of both methods of administration goes, I have found that the results are very similar; the advantage of the intravenous over the intramuscular consisting in its comparatively painless action. The first case (intramuscular), on Jan. 25th, was that of a young man, aged 20 years, suffering from mucous patches of the soft palate, tonsils, and base of the uvula, following an unhealed primary lesion of the inner surface of the prepuce. On Feb. 3rd the mucous patches had all cleared up. The sore had also cicatrised. So far, in his case, there has been no relapse. Case 2: Indurated sore on the sheath of the penis; papular eruption on the chest, abdomen, legs, and forehead; mucous patches of the right tonsil and sides of the tongue. Within ten days the mucous lesions had all cleared up. The skin eruptions, which were the last to disappear, had faded away within a fortnight. The patient was sent to me by Dr. G. S. Wilde of Bootle, and proved a most interesting case. Case 3: A young married woman, suffering considerable pain in the mouth due to irritating mucous patches of the tonsils, tongue, and lips. All the lesions cleared up within a week, "as if by magic," to make use of her own expression.

There is no need to multiply the early cases of secondaries in which the salvarsan was used; all, with one exception, and in that a very slight relapse, followed much the same

benign course. A noteworthy case was an early perionychia (five months' infection), in which four fingers on one hand and one toe were affected. The inflammation at the base of the nails was considerable, involving the greater part of the fingers and toe and causing much pain. On Feb. 3rd I administered an intramuscular injection. On Feb. 20th all the inflammation had subsided, leaving the fingers and toe quite normal. The nails had nearly all separated and a new growth was visible. The patient had also had some mucous patches on the lower lip, which disappeared at a much earlier stage.

Another very interesting case was that of a man 40 years of age, suffering from a gummatous syphilide of the mouth (12 years' infection), giving rise to much destruction of tissue at the angles of the mouth and lower lip, causing disfiguration and contraction of the mouth. A very satisfactory improvement (by the same means) was visible in a few days. The ulcerative and degenerating processes were arrested, cicatrisation following kindly. The patient was a week in the isolation ward, and returned to his home in the country very pleased with the improved appearance of his mouth, which on admission to hospital was revolting to look upon. He wrote to me recently saying that he had had no relapse so far.

In three very distressing cases of leucoplakia (all of some years' duration), in which the tongue presented a very angry appearance, the changes which had taken place in the submucous tissue caused the affected part to become more prominent and nodular. In two of the cases the fissures on the dorsum and sides of the tongue, with the loss of pliability of the organ due to its hypertrophied condition, caused the patients much distress and sensitiveness to hot fluids and spicy food. Within a week of the administration of salvarsan the improvement was marked in all three cases. One of the patients said that he "could now eat a brick." The first of these three cases had a slight relapse two months after the intramuscular injection when it was thought wise to give him a second dose, which was intravenously administered. I saw this man at the department in company with Mr. F. P. Wilson on July 5th, and the tongue then presented a very satisfactory appearance; the fissures at the sides of the tongue had all disappeared, and he said he could now eat with comfort. In three cases of hoarseness due to some secondary lesion of the vocal cords, the loss of voice disappeared very soon after similar treatment, the improvement being marked. One of the pleasing features of the cases treated by means of salvarsan is the enthusiasm shown by the patients as to the value of the compound. This fact must have come to the notice of others who have had experience of its action in cases of syphilis. The last case to which I need allude was one of neuritis (ataxic symptoms). The patient had improved somewhat under mercurial inunctions. However, I advised him to submit to an intravenous injection, to which he consented. In ten days his condition had markedly improved. The gait was much steadier. He expressed himself "a different man."

At the department the practice now is to keep the patients (treated by salvarsan) for some further period under mercurial treatment. I am much indebted to Dr. T. R. Bradshaw for the use of an isolation ward in the Royal Infirmary for the cases treated intramuscularly. I am also much indebted to Mr. R. E. Kelly for operating in some of the intravenous cases. Also to Dr. A. Adams (Dr. Bradshaw's late house physician), Dr. R. B. Edwards (my late house surgeon), and Dr. L. Buckley (my house surgeon) for their kind assistance with the cases, some of which were efficiently injected by them.

I am, Sir, yours faithfully,

ARMAND BERNARD, B.A., M.B.,
Surgeon to the Department for Specific Diseases at the Liverpool Royal Infirmary; Lecturer in Specific Diseases at the University of Liverpool.

July 7th, 1911.

To the Editor of THE LANCET.

SIR,—I am at a loss to understand the motive underlying Mr. Ernest Lane's letter in your last issue, and which appears to be personal rather than critical. He acknowledges that I was correct in my surmise that, when he spoke adversely of salvarsan in December last, his experience was a small one. He also assures me that "he had not the time or the inclination to carefully glean anything" either from the reported casualty lists or the writings of the opponents or friends of salvarsan treatment. Mr. Lane writes that it passes his understanding that his allusion to what I called a remarkably small casualty list should be considered hostile criticism. Mr. Lane, however, drew attention to, and insisted on, the danger to life and sight following the use of this drug, and stated that "intolerance to mercury would be the only justification for looking elsewhere for a remedy." Mr. Lane did *not* emphasise the smallness of the casualty list; on the contrary, he by inference suggested that it was so large as to contra-indicate the treatment in all but occasional cases. Major French, to whose article of June 24th I was replying when I referred to Mr. Lane, quotes Mr. Lane as writing: "My experience of '606' does not agree with the opinions of the majority of those that have tried that preparation, and I am not at all inclined to advocate its use."

When an authority of the eminence of Mr. Lane speaks with no uncertain voice before a medical society on the question of the treatment of syphilis he surely cannot expect or wish his opinion to pass unnoticed. I have the high authority of Professor A. Neisser for entirely disagreeing with Mr. Lane's opinion on the undesirability of the routine use of salvarsan. Professor Neisser said in the Cavendish lecture: "We must treat every fresh case of syphilis, and, indeed, every case where we have suspicion of it, as quickly and as energetically as possible with '606.' Up to the present salvarsan has certainly proved less injurious to the internal organs than mercury."[1] Mr. Lane says that he is shortly opening a discussion on the treatment of syphilis by salvarsan. I shall read the report of this discussion with great interest, and perhaps may hear that Mr. Lane has modified his opinion of December last, which, according to his own confession, was based on only a brief personal experience and an incomplete study of the literature.

It is, perhaps, to be regretted that such an eminent authority should have permitted himself to express a decided opinion based on insufficient data.

I am, Sir, yours faithfully,

HUGH WANSEY BAYLY.
Upper Berkeley-street, W., July 15th, 1911.

THE DECLINING BIRTH-RATE.

To the Editor of THE LANCET.

SIR,—Captain O. A. R. Berkeley-Hill's comments from India in THE LANCET of July 8th on my Jenner lecture[2] are doubly welcome, not only for their intrinsic value but also for their reminder of the late Mr. Berkeley-Hill's unstinted labours in connexion with the Contagious Diseases Acts. The problem of the birth-rate is nearly connected with the prevention of venereal disease. These questions are of the very first national importance; they can hardly be adequately discussed except by medical men, and by them they are seldom discussed except as an *hors d'œuvre* and in private. They should, on the other hand, be expounded to every student during his course, and my own lecture was intended not as an *ex cathedrâ* utterance, but as an appeal for thought and inquiry.

Captain Berkeley-Hill's points may be answered as follows:—(*a*) He thinks I "greatly overrate the disorders indubitably referable to the prevention of conception." My opinion was based on that of the late Professor J. W. Taylor,[3] and we must both appeal to gynæcologists to corroborate or revise his experience. (*b*) Commenting on my plea for sexual discipline, Captain Berkeley-Hill mentions the "many cases of chronic mental disorder which are directly attributable to sexual repression." We must appeal to specialists in mental diseases. But one must beware of attributing mental results to sexual repression, when they may be due to inherent mental defect, and when the repression may be due to habit, circumstance, or submission to authority, itself the result of such defect. My present opinion is based on that of Sir W. Gowers, who declared that he believed no one to have suffered in health by sexual abstinence. (*c*) Methods for prevention of conception may be checked by law without being prohibited. Their price may be raised by fiscal methods; their sale limited, like that of poisons, and subject to medical prescription. (*d*) I cannot understand Captain Berkeley-Hill's phrase, "compulsory

[1] West London Medical Journal, July, 1911, pp. 171 and 173.
[2] THE LANCET, April 22nd, 1911.
[3] Brit. Med. Jour., Feb. 20th, 1904.

barrenness," nor follow Mr. Bernard Shaw's antics amongst the marriage-laws; nor agree that the medical profession must first attack the "lamentable state of the English marriage and divorce laws." Let Captain Berkeley-Hill explain his objections and his alternative.

Does he think that middle-class women refuse to marry because the marriage service follows general custom and expediency in prescribing that man, as breadwinner and protector, shall be the responsible head of the household? Or that they refuse to bear children because they have fallen in love with another man, while their husband remains faithful? Or is he opposed to monogamy or perhaps to any marriage tie as the essential preliminary to propagation in the eyes of the law? If so, he is against civilisation and neither he nor Mr. Shaw has proved his point.

Pending such proof, Sir, I would submit that the chief and obvious factors in the decline of the birth-rate are: (1) the knowledge of methods of prevention and the ignorance of its results; (2) competition in every detail of life and the consequent economic stress; (3) indulgence and lack of discipline; or, in other words, the rational, the economic, and the moral factors. As medical men we are concerned only with the rational factor and should insist, both in public and private, on the value of nature's own checks and methods; on the dangers of celibacy, prostitution, and abnormal married intercourse; and on the healthy influence, the gaiety, and the ultimate economic value of a well-stocked nursery. Contrary advice must only be given with a due sense of the personal and public dangers entailed. May I appeal to gynæcologists and to experts in mental diseases on the two points raised?

I am, Sir, yours faithfully,

F. E. FREMANTLE.

Zetland House, by Guy's Hospital, S.E., July 10th, 1911.

SUGGESTED DIAGNOSIS OF MALIGNANT SCARLATINA ANGINOSA.

To the Editor of THE LANCET.

SIR,—Surely the case reported in THE LANCET of July 15th by Mr. Ernest Stratford, of Wellington College Station, was one of malignant *scarlatina anginosa?* Unfortunately, neither is the date on which the child sickened given, nor are the initial symptoms of the attack mentioned. Again, there is only one note as to the pulse-rate. Notwithstanding these drawbacks, in attempting to arrive at a diagnosis, the confluence of the rash, intensity and persistency of the fever, "enormous" swelling and subsequent sloughing of the tonsils, the presence of hæmaturia and of œdema of the feet, all go to make up a very graphic description of scarlatina maligna.

I am sure that all published descriptions of rötheln will be appealed to in vain—Mr. Stratford, in fact, admits as much—to substantiate a diagnosis of that acute infection in the terrible case reported in your columns.

I am, Sir, yours faithfully,

Dublin, July 15th, 1911. JOHN W. MOORE, M.D. Dub.

AN UNKNOWN SAMARITAN.

To the Editor of THE LANCET.

SIR,—I should like through the medium of your columns to express my grateful appreciation of the kindness shown me last Sunday in Wandsworth by a doctor (whose name I do not know) who not only rendered me first-aid when I was suffering from the effect of a spill from my cycle but brought me home in his own car. I trust you will allow me to take this opportunity of thanking him very sincerely.

I am, Sir, yours faithfully,

8, Solon-road, Brixton, S.W., July 17th, 1911. A. E. POOLEY.

INCOME-TAX RETURNS AND THE DEPRECIATION OF MOTOR-CARS.

To the Editor of THE LANCET.

SIR,—I shall be glad to know whether a doctor may claim for depreciation of a motor-car used in carrying on his practice in making up the return for assessment of the income-tax? My practice has just been assessed by the Special Commissioners and they have disallowed this item, stating that the depreciation of machinery is only allowed in trades and not in professions. If this is the case surely it is time that such unjust law was rectified. The car is indispensable to the production of the income. If a car or carriage were hired the expense could be deducted.

I am, Sir, yours faithfully,

July 10th, 1911. PUZZLED.

*** We understand that it is not infrequently the practice of surveyors to disallow claims for depreciation on the grounds suggested by our correspondent. Some surveyors, too, disallow the claim for the cost of a new car to replace one worn out. We have been advised by the Income-tax Repayment Agency that "a doctor may charge in his accounts for income-tax purposes all repairs to his motor-car used in his practice, and for the cost of a new car to replace the old one." It is obviously unfair to disallow the claims both for depreciation and for renewal: one or the other should stand; and if the practice to disallow both is growing medical men should combine to resist the injustice.—ED. L.

OPENING OF THE NEW MEDICAL BUILDINGS OF McGILL UNIVERSITY, MONTREAL.

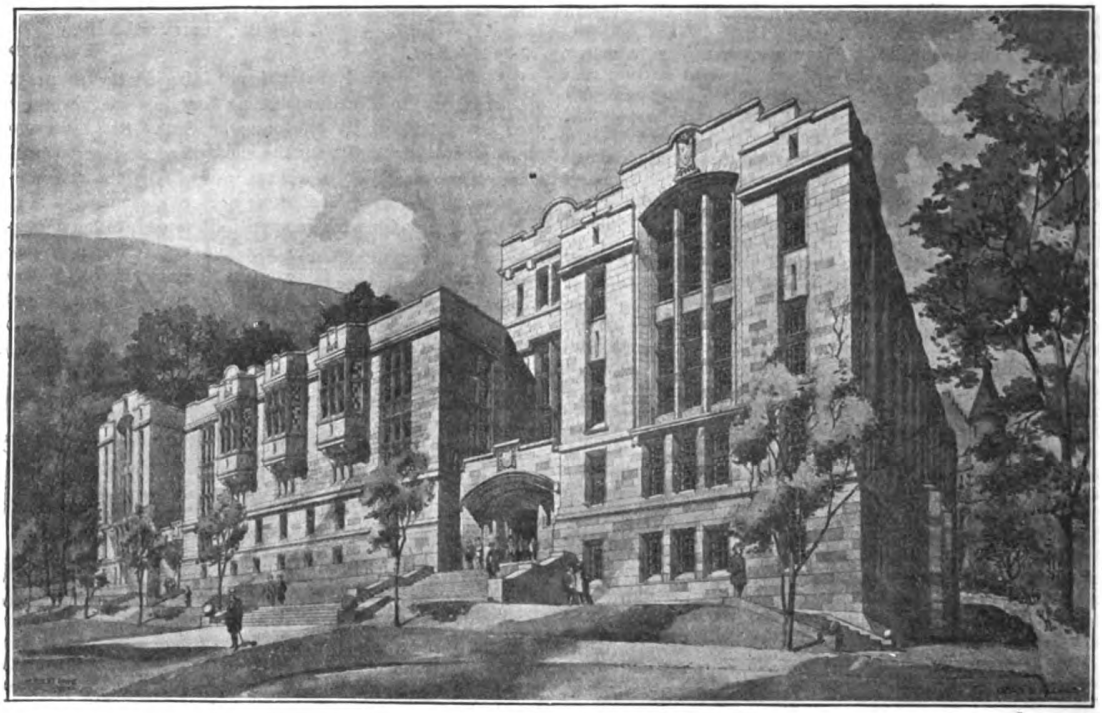
(FROM A SPECIAL CORRESPONDENT.)

THE week beginning June 5th was a carnival week for medicine in Montreal. The first two days of the week were devoted to celebrations in connexion with the opening of the new medical building of McGill University, and on the three following days the annual meeting of the Canadian Medical Association took place in the same building. These events, which have already been chronicled,[1] were made the occasion for a great gathering of McGill medical graduates from almost all parts of the continent, as well as from several out-of-the-way regions, and I think it likely that your readers will be interested in a brief account of the functions.

The attractive programme arranged for the opening of the new medical building was carried out without a hitch, reflecting great credit upon those responsible for the management of affairs. A conversazione was held in the evening of the opening day in the new medical building, and comprised many features of scientific and social interest. There were microscopical and bacteriological exhibits, Roentgen ray exhibits, exhibition of liquid air, library exhibits, lantern demonstrations and exhibits in the hygiene laboratories, and micro-projection of biological specimens, models, and experiments illustrating the physiology of the special senses. Music, concerts, and an informal dance were provided. The main interest of the evening's proceedings, however, naturally centred in the opening ceremony by the Governor-General of Canada, Earl Grey, which took place at 9.15 in the anatomical laboratory, a magnificently proportioned and large room on the third floor. Upwards of 2000 guests were present, comprising the leaders of social and professional life in Montreal. Upon the platform, among other university and city dignitaries, were Dr. Peterson, the principal of the University, Dr. Shepherd, dean of the medical faculty, and Professor J. G. Adami, professor of pathology in the University. After Dr. Peterson and Dr. Shepherd had welcomed their excellencies, Earl Grey delivered an apt and eloquent address, in the course of which he announced that Lord Strathcona had cabled from England that he would give a further sum of £20,000 in order that the new building might be equipped in a fitting manner. This makes a sum of £110,000 given by Lord Strathcona towards the cost of erecting and equipping the new building, in addition to providing the magnificent site. Indeed, without the aid of Lord Strathcona the aspirations of the medical faculty as regards building and equipment could not have been realised. The building, as will be seen from the accompanying illustrations, both in construction and arrangement, is commensurate with the great reputation of the medical school of McGill University. A striking feature of the building is the library, to which Sir William Osler and Dr. Casey Wood of Chicago

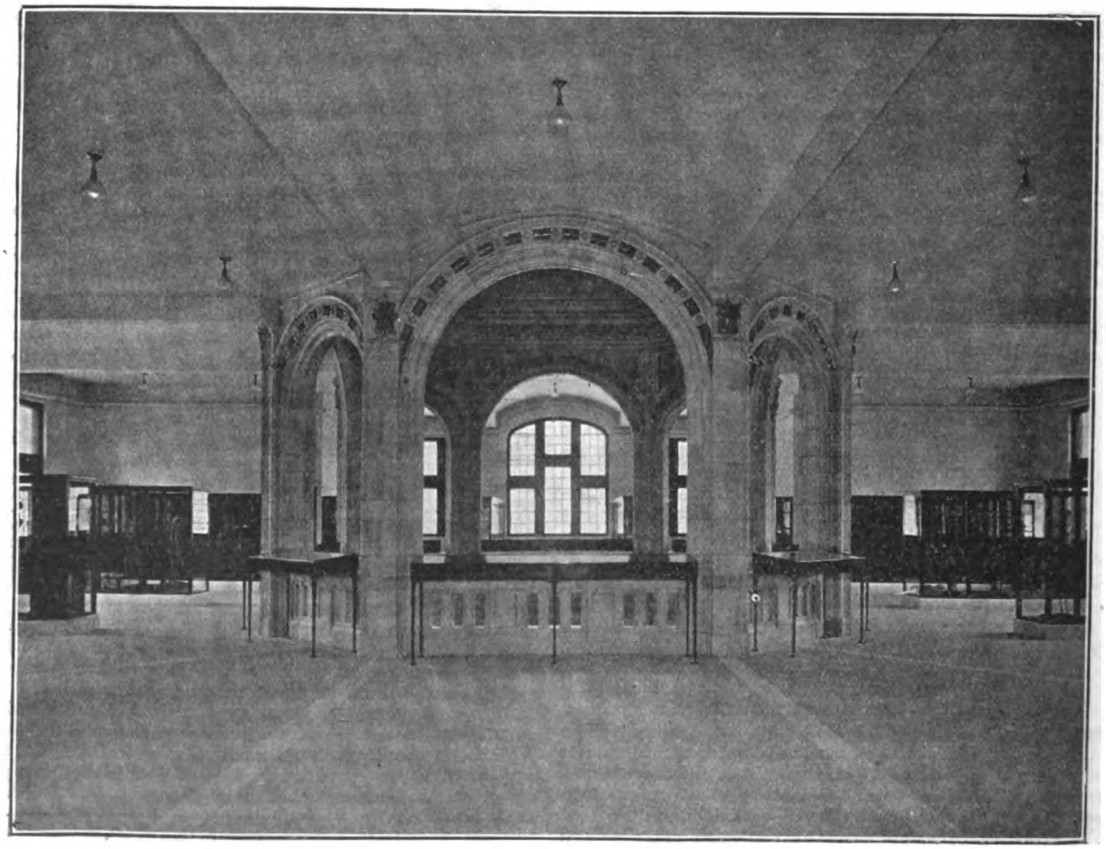
[1] THE LANCET, July 8th, 1911, p. 125.

FIG. 1.



McGill Medical College.

FIG. 2.



Anatomical museum McGill Medical College.

have made some extremely valuable gifts. The excellent arrangements of the library are mainly due to the energy of Miss Charlton, the acting librarian.

On Tuesday morning, June 6th, Earl Grey laid the corner stone of an addition to the General Hospital, Montreal. This hospital is to be virtually rebuilt, and owing to the lim ited space available (for it is situated in the heart of the most crowded district of Montreal) the new buildings will be erected to a height of about seven storeys. These will be of steel construction throughout. The steel skeleton of the part to which Earl Grey laid the corner stone has already been put in place and requires only its casing of stone to be complete so far as the exterior is concerned. At this ceremony the leading civic and university officials were present, and Earl Grey gave an especially appropriate and feeling address.

The culmination of the festive portion of the programme was reached on Tuesday evening, with a dinner at the Windsor Hotel, given by the dean, professors, and members of the teaching medical staff to the medical graduates of McGill University. At this also the Governor-General was present, and there were more than 500 guests, including graduates from the year 1854, represented by Sir James Grant of Ottawa, up to those of the present year. Probably the most distinctive of the speeches was that by Dr. Adami, who took the opportunity to criticise severely some recent remarks and writings of Mr. Bernard Shaw anent the medical profession. Dr. Adami characterised as wicked some of Mr. Shaw's animadversions on the medical profession—wicked because, being widely read by the unthinking crowd, some of the mud cast by Mr. Shaw was sure to stick. From all standpoints the celebrations in connexion with the opening of the new medical building of McGill proved a great success. Before leaving the subject of McGill University Medical School it will be as well to refer to a point which was constantly emphasised in the speeches —viz., that the medical part of the University is considerably hampered by poverty. The impression appears to be general that the medical school of McGill University is rich. This is far from being the case. As Dr. Shepherd stated, while it is rich in buildings and equipment, it is wretchedly poor in endowment. According to the dean of the medical school, at least £200,000 are needed for endowment. There is no endowment for the chairs of anatomy and chemistry, and that of the other chairs is insufficient. Research fellowships also are needed, as well as a library and museum fund. Dr. Shepherd appositely said: "We are living in a palace, but we are starved."

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Faculty of Medicine in the University.

THE dean's annual report for the session 1910–11 has been recently presented to and approved by the Medical Faculty. During the past session the number of students entering for courses in the Faculty of Medicine has been well maintained, and the total is 35. They are divided as follows: 24 have entered for the degree of the University, 3 for degrees in other universities, 2 for the diploma of the London Conjoint Board, and 6 for those of other examining bodies. The following are the entries of the last six years. The total for 1910–11 is 35; for 1909–10, 34; for 1908–09, 30; for 1907–08, 35; for 1906–07, 37; and for 1905–06, 27. The total number of undergraduates at present in the school is the largest on record—viz., 148. 188 students other than undergraduates have taken courses: in research work, 41; school of hygiene, 31; tropical school, 49; operative surgery, 3; and dental, 64. The total of all classes is therefore 336, compared with 298 during the previous session. The proportion of students preparing for the degree continues to increase. The first M.B. classes have been larger during the past session than they have ever been. Progress has been made throughout the past session in the remodelling of first year subjects to form a more suitable introduction to the later subjects of the curriculum. The changes have been most marked in chemistry. Zoology and botany have also been modified in the same direction. A recent regulation of the General Medical Council regarding courses of instruction in these subjects for the First Professional Examination has engaged the attention of the Faculty, and on its recommendation the University Council is about to address a memorial to the General Medical Council in the matter. The course of instruction in systematic surgery has for the first time been divided into general and regional, and the board of clinical studies has also instituted a new course for junior students preparatory to the commencement of dressing and clerking. The composition fee has been remodelled so as to include all the courses of instruction necessary for the degree except vaccination and out-door midwifery. It is now possible to pay the fee in four instead of three instalments. The faculty has devoted considerable attention to the proposal to institute degrees in hygiene. It has recommended to the Senate and the Council the institution of the degrees of Bachelor of Hygiene and Doctor of Hygiene, but these proposals have not yet received the assent of those bodies. A diploma in ophthalmic surgery has been instituted for graduates, and ordinances and regulations relative to the same have been approved by the Senate and Council. The course of instruction in this direction has aroused considerable interest, and applications for admission have already been received. The school of pharmacy has also shown signs of a renewed activity. The Faculty of Medicine is now recognised by the Board of Education as a school eligible for grants. The faculty has had to deplore the loss of one of its most distinguished members, Sir Rubert Boyce, and has recorded on its minutes its admiration of the great services he rendered to medicine and to the University. The most notable appointment in the faculty during the session has been that of Mr. R. Newstead to the newly established chair of entomology. This chair was founded in memory of Joseph Everitt Dutton, who lost his life while on an expedition of the School of Tropical Medicine in West Africa. On the recommendation of the Senate, and with the approval of the Faculty of Medicine, the Council conferred the title of associate professor on Dr. Ernest E. Glynn, the lecturer in clinical pathology. On the recommendation of the faculty an alteration has been made with regard to the regulations for the William Mitchell Banks Memorial lectureship. The election will in future be made biennially instead of annually as heretofore. Alterations in regulations have also been made regarding the award of the International and Colonial Fellowships, the University Scholarship, the Senior Lyon Jones Scholarship, and the medals in anatomy and physiology.

Liverpool University.

On July 8th the Vice-Chancellor of Liverpool University admitted to the University the numerous candidates on whom degrees had been conferred. In his address Sir Alfred Dale paid tributes to the late Sir Rubert Boyce and Professor Kuno Meyer, the latter having been transferred to Berlin. He pleaded for two gifts of £5000—one to enlarge the chemical laboratory, and the other to complete the club-house of the Undergraduates' Union. The scene was a brilliant one, and the function proved highly interesting.

Woolton Convalescent Institution.

Cordial eulogy was bestowed upon the operations of the Woolton Convalescent Institution at its thirty-seventh annual meeting held recently. It was announced that a valuable collection of pictures and furniture had been bequeathed to the institution under the will of the late Madame Otterburg, of London, sister-in-law of the late philanthropist, Mr. David Lewis.

The New Laboratories at Mill-road Infirmary.

A suite of laboratories in connexion with Mill-road Infirmary, an institution under the control of the West Derby board of guardians, was opened on July 14th by the chairman of the infirmary. The infirmary contains 900 beds, and the new research laboratories are designed for the investigation of disease. The arrangement of the laboratories, which are fitted up with all the necessary and most up-to-date appliances, will admit of clinical, bacteriological, and pathological investigation. This departure is the first of the kind which has received the sanction of the Local Government Board. At the conclusion of the opening ceremony the committee and guests were entertained to luncheon by Dr. Nathan Raw, the medical superintendent of the infirmary.

July 17th.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

Medical Inspection of School Children.

THE Bristol school medical officer's annual report contains much that is of interest; certainly it affords ample evidence in favour of the claim made by the medical officer, Dr. T. A. Green, that "our system of medical inspection, with its gradual expansions, seems to be working satisfactorily." It is, indeed, striking to note in how many directions expansion and coördination with other organisations are taking place. The two school nurses have worked during the year under Dr. Green's direct supervision; a large portion of their time has been occupied in the treatment of verminous and dirty children. In addition to this they have given help at the five "ringworm centres" established last year by the education committee. These centres are for the inspection of children suspected to be suffering from ringworm and for treatment in necessitous cases. The establishment of the centres was the outcome of a resolution excluding cases of ringworm from the schools. The Children's Care Committee is a voluntary body, consisting of the 51 lady visitors for the council and voluntary schools. These visitors have investigated 2608 cases in which the advice of the school medical inspector was ignored; and in no less than 40 per cent. of these the parents have been persuaded to secure treatment for their children. A "semi-deaf" class has been established for the education of children who, while having the power of speech and a certain amount of hearing, were too deaf to gain full advantage from the routine education. 22 children have been attending this class, with satisfactory results on the whole. During the year there were 1323 cases of notifiable infectious disease, and 2182 of non-notifiable disease (measles, whooping-cough, mumps, chicken-pox, and "suspicious" cases) in the schools. Finally, it is encouraging to note a fall in the percentage of carious teeth and of verminous heads as compared with last year.

Coronation Celebrations at Bristol.

Several of the medical institutions of Bristol used special means for celebrating the Coronation of King George V. At the Lesser Colston Hall the blind people of Bristol met, together with the children from the new School of Industry for the Blind, to receive Coronation chocolate boxes and to hear a selection of band music. The company was gratified to learn that the King had graciously consented to confer the title of "Royal" on the School of Industry. At the Ham Green Fever Hospital there was a garden party, with the presentation by the health committee of the city council of an illuminated address to Miss Watt, who has just resigned the post of matron to the Novers-hill Fever Hospital. At the Royal Infirmary sports were held, the prizes being given away by Mrs. E. H. E. Stack.

The Lectureship in Botany to Bristol University.

The lecturer in Botany, Mr. J. H. Priestley, has been appointed to the professorship of botany in the University of Leeds. He will be greatly missed, not only in the botanical department, where he has organised research into problems of plant growth and stimulation, but also in connexion with student societies and organisations. He has been secretary to the local naturalists' club, and to the University athletic ground committee, and president of the University Botanical Field Club. In addition to these offices he has done much of the organisation of the department of economic biology and of the guild of undergraduates.

A Parish Patient at Tavistock.

At a meeting of the Tavistock (Devon) board of guardians held recently it was stated that one of the district medical officers had attended a man who had obtained a "medical order" for several weeks. Upon his death it was discovered that he had over £100 in the bank. The medical officer is now making a claim against the estate of the deceased for medical attendance, and the guardians have decided to assist him in obtaining his fees.

Blindness and Untrained Midwives.

The session of the International Conference on the Blind was held at Exeter on July 7th, under the presidency of Sir Robert Newman. The honorary general secretary (Mr. C. Collingwood), in the unavoidable absence of Dr. G. Reid, the medical officer of health of Staffordshire, read his paper on "Untrained Midwives." Dr. Reid in the course of his interesting remarks alluded to the blindness which resulted from the neglect of untrained midwives attending lying-in cases. He added that with intelligent care of the infant ophthalmia should hardly ever occur, and if such cases should arise, simple, efficient, and early treatment would practically cure every case. Dr. Reid advocated the compulsory notification of this disease, and after the discussion which followed a resolution to that effect was passed.

The West Cornwall Infirmary, Penzance.

At the last meeting of the committee of the West Cornwall Infirmary, Penzance, a letter was read from Mr. R. F. Bolitho, enclosing a cheque for £1500, to be devoted towards the endowment of a bed, to be named the "Oliver Caldwell Bed," in memory of the architect of the infirmary. Mr. Bolitho states that the gift "is to assist to celebrate locally and loyally the Coronation Day of King George V."

A Medical Officer of Health for East Devon.

At the last meeting of the Honiton town council it was reported that the Local Government Board had stated that it had decided to issue an order for uniting the borough of Honiton, the urban districts of Ottery St. Mary, Seaton, and Sidmouth, and the rural districts of Axminster and Honiton, into a sanitary district, with one medical officer of health for the whole area. The Local Government Board added that the medical officer appointed must devote his whole time to the duties, and suggested that he should also be assistant medical inspector of school children.

July 18th.

WALES.

(FROM OUR OWN CORRESPONDENT.)

Typhoid Fever in the Crickhowell Rural District.

DURING the past few weeks there have occurred six cases of typhoid fever, two terminating fatally, in the Llanelly parish of the Crickhowell rural district in Brecknockshire. The medical officer of health, Mr. P. E. Hill, attributes the outbreak to the pollution of the water-supply by the Brynmawr sewage, the outfall works of the Brynmawr urban district council being situated in Llanelly. As long ago as 1902 Dr. R. J. Reece and Mr. Sandford Fawcett, M.Inst.C E., reported to the Local Government Board upon the unsatisfactory condition of these sewage works. On the occasion of the visits of these inspectors leaking sewage pipes were found which undoubtedly polluted certain water-supplies, and in his most recent inquiries Mr. Hill has found that a similar condition prevails and bacteriological examination has revealed the presence of B. coli in the supplies.

The Welsh Crusade against Consumption.

At a meeting held at Shrewsbury of the executive committee of the Welsh National Memorial to King Edward VII, Mr. David Davies, M.P., who suggested the form which the memorial should take, stated that the principal work carried on by the committee during the past eight months had been the collection of funds and the education of the public in the prevention and cure of tuberculosis. The total sum already promised is nearly £190,000, and investments of moneys actually received are yielding an income equal to £3000 per annum. It is hoped that the current administrative expenses will be met out of interest on invested funds. A travelling exhibition has visited nine towns in South Wales and nine in North Wales, and over 200 public meetings have been held in various parts of the country. The committee suggests that provision should be made in the National Insurance Bill for the constitution of Wales and Monmouthshire, so far as the provision of sanatoriums and other institutions for the treatment of tuberculosis and the administration of sanatoriums are concerned, a separate unit under an association to be incorporated by Royal Charter and to be called the King Edward VII. Welsh National Memorial Association. The committee is so sanguine that with properly organised effort tuberculosis can practically be stamped out that a further suggestion has been made for the utilisation of the funds of the association when this shall have occurred. It was therefore resolved by the committee that as tuberculosis is inseparably connected with the general

health of the nation the proposed association should be empowered to take such steps as might be deemed advisable to improve the general health of the people of Wales and Monmouthshire.

Heavy Fines upon Milk Vendors.

At one time the amount of the fines which were imposed upon milk vendors in South Wales for selling milk of an inferior quality was so ridiculously small that no deterrent effect was produced. Latterly, however, the magistrates before whom such cases have been brought have realised that to be effective the fine must be a substantial one. At Pontypool recently a fine of £20 was imposed upon a dairyman, a sample of whose milk taken from a cart in the street was found to contain 4·23 per cent. of added water. Still more recently the stipendiary magistrate of Aberdare imposed a fine of £50 upon a dairyman for a similar offence.

Tregaron Rural District Council and the Local Government Board.

In the report upon the sanitary condition of Tregaron rural district, which was issued by the Local Government Board in 1907, Dr. E. P. Manby referred to the inadequacy of the salary paid to the inspector of nuisances, who was expected to devote the whole of his time to the duties of the office for the small sum of £40 per annum. The Board refused to sanction the appointment, whereupon the district council reduced the salary to £30. For nearly four years correspondence has been going on between the council and the Board, the central authority persisting in its refusal to sanction any salary lower than £60 per annum, the sanction carrying with it a payment of one-half that sum from the Exchequer grants. At length the council has acquiesced in the demand of the Board, whose persistence should act as a deterrent to other sanitary authorities who desire to cut down the salaries of their officials to the lowest possible point. A more reasonable attitude has been taken in neighbouring Herefordshire by the Kington urban district council, which has increased the salary of the medical officer of health, Mr. R. Harding, from £20 per annum to £40, and has increased the salary of the inspector of nuisances by £10 owing to the additional work entailed upon these officials by the Housing, Town Planning, &c., Act, 1909.

July 19th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Farewell Banquet to Colonel and Mrs. Warburton.

ON the evening of July 14th a banquet was given in honour of Colonel W. P. Warburton, I.M.S., C.S.I., superintendent of the Edinburgh Royal Infirmary, and Mrs. Warburton, in the Caledonian Hotel, by their medical friends in Edinburgh on the occasion of their leaving the city. Dr. and Mrs. Byrom Bramwell and Dr. and Mrs. George A. Berry received the guests, and Sir William Turner presided at the banquet, which was attended by a large number of the staff of the Edinburgh Royal Infirmary as well as other representative members of the medical profession and a number of ladies. Sir William Turner proposed the health of "Colonel and Mrs. Warburton" in a felicitous speech. He referred to the career of Colonel Warburton, first at the University of Edinburgh and later in India, and assured Colonel Warburton of the high appreciation with which his work at the Royal Infirmary was regarded by all with whom he had come into contact. Sir William Turner then presented to Mrs. Warburton as a memento of the occasion an album in which those attending the banquet had signed their names.

Edinburgh Royal Infirmary.

At a meeting of the managers of Edinburgh Royal Infirmary, held on July 10th, Dr. William Thomas Ritchie was appointed an assistant physician to the institution. Dr. Dawson Turner, on the completion of two terms of service of five years each as medical electrician to the Royal Infirmary, has now been appointed Extra Medical Electrician. The duties attached to the office are the treatment by radium of any cases that may require such treatment. No similar appointment appears yet to have been made in this country. Dr. W. Hope Fowler has been appointed to succeed Dr. Dawson Turner as Medical Electrician, and Mr. Archibald McKendrick becomes the Junior Medical Electrician.

Edinburgh Hospital for Women and Children and the Hospice.

The new wing of the Edinburgh Hospital for Women and Children, which has just been completed, was, on the occasion of the Royal visit to Edinburgh, honoured by a visit from Her Majesty the Queen. The hospital, which was founded by Dr. Sophia Jex-Blake, and is officered by medical women, will now have accommodation for 40 patients. The contributory system will still be maintained, the patients paying from 5*s.* to £2 2*s.* per week. The new wing contains two wards of 14 beds each, with wide verandahs facing west and running the whole length of the wards, a new and up-to-date operating theatre, a dispensary, and other offices. The older part of the building, consisting of smaller rooms, will be used for the accommodation of patients paying the higher rates of board, and on the ground floor of this section an electrical department has been fitted up. During the past year the medical women in Edinburgh have wisely strengthened their position by the amalgamation of the hospital with the Hospice, an institution also officered by medical women and situated in the thickly populated district of the High-street. The Hospice will now be reserved entirely as a maternity home for poor married women and a centre for a maternity out-patient department, while all surgical and medical cases will in future be treated at the hospital, the situation of which, at the corner of Whitehouse Loan, provides a fresher atmosphere and more pleasant surroundings than were to be found in the centre of the city.

Carnegie University Fees.

Few who have been watching the trend of events at the Scottish Universities during the last few years have been surprised by the announcement which has just come from the Trust Offices regarding a modification in the payment of Carnegie University fees. Every year since their institution the number of students who take advantage of the benefits of the scheme has increased—particularly in the case of women undergraduates—and the Trust has been faced with the question of modifying the scale. Those modifications, however, will apply only to students who become beneficiaries for the first time next session, present beneficiaries not being affected, but the new arrangement will not seriously embarrass the recipients. It is not expected that the new order of things will become a permanency, and the supposition is that the whole scheme of fees will shortly form the subject of reconstruction. At the University of Glasgow, taking the respective faculties in the bulk, it is estimated that a little over 50 per cent. of the whole fees are met by the Carnegie Trust. As the demands for payment of class fees have this year considerably exceeded the available income under Clause B, the executive committee of the Trust has announced the following arrangement for the academic year 1911–12. In the case of present beneficiaries it hopes to be able to continue the payment of class fees as formerly, but in the case of new beneficiaries it does not see its way to exceed the following annual allowances for the various faculties: Arts, £9; science, £12; medicine, £15; law, £6; and divinity, £6.

Incidence of Puerperal Fever in Glasgow.

In his report on the occurrence of puerperal fever in Glasgow, Dr. A. K. Chalmers, the medical officer of health of the city, points out that the Notification of Births Act now enables us to review the incidence of puerperal fever in some detail. Of the 113 cases of the disease registered last year, 31 had been under medical care from the beginning, while 82 were attended by midwives at the onset of labour, although in 19 of these medical assistance was subsequently obtained. Or, to put it differently, of 10,399 births attended by medical men, the patients in 31 cases contracted puerperal fever, making a rate of 3 per 1000 births; on the other hand, of 12,446 births attended by midwives alone, in 82 cases puerperal fever occurred, making a rate of 6 6 per 1000 births. Dr. Chalmers, however, draws attention to this fact, that before regarding these rates as final, and more particularly before accepting the greater relative incidence of puerperal fever in cases attended by midwives as resulting from defective technique, it is necessary to remember that the midwives' practice is more frequently among the poorer classes and in the smaller

houses, and that these are factors which, while incapable of express statement, must be taken into account when considering the difference in the incidence.

Greenock and District Combination Hospital.

According to the annual report just issued, the past year has been memorable as the busiest experienced in this hospital. This was altogether due to the great prevalence of scarlet fever, which was epidemic in Greenock and the surrounding districts. At times, indeed, the scarlet fever block, which is the largest in the hospital, was taxed beyond its utmost capacity, and the overflow had to be accommodated in the discharge block. During the year 566 cases, of which 448 were scarlet fever cases, were admitted; of these 34 died, giving a mortality of 6 per cent. The average duration of residence in hospital was 43·9 days and of fatal cases 12·2 days.

University of Aberdeen.

The summer graduation at the University of Aberdeen took place on July 12th. The degree of M.D. was conferred upon 8 persons, Ch.M. upon 1, M.B., Ch.B. upon 11, and the diploma of public health upon 6. In his speech Principal Smith noted the fact that the number of students who matriculated in the present year—namely, 969—was 38 less than last year. He also referred to the various gifts to the University made during the year and to the retirement of Sir W. Ramsay, professor of humanity in the University. The University Court has appointed the following to be additional examiners in the respective subjects:—Materia Medica: James Burnet, M.A., M.D., M.R.C.P., lecturer in materia medica and therapeutics, Edinburgh. Pathology: James Miller, M.D., D.Sc., lecturer in pathology, Royal Colleges, Edinburgh. Surgery: Alexander Don, M.A., M.B., C.M., F.R.C.S., lecturer in clinical surgery to the Royal Infirmary, Dundee.

Baldovan Asylum: Change of Name.

Intimation was ordered by the First Division of the Court of Session on June 28th of a petition by Bishop Robberds of Brechin, the Primus of the Episcopal Church in Scotland, and others forming the general council of the Baldovan Asylum for Imbecile Children. The asylum was founded in 1853, under the patronage of the late Queen Victoria and the Prince Consort. From their experience the petitioners find that the name of the institution, and especially of the words "asylum" and "imbecile," is regarded as objectionable by parents of many children who should become patients in the institution, so that the parents often decline to send their children there, thus seriously interfering with the usefulness of the institution. The petitioners are of opinion that the name should be changed to the Baldovan Institution for the Treatment of the Feeble-minded. The proposal to change the name has been submitted to the General Board of Lunacy for Scotland, which has approved of it, and to the general council and subscribers to the institution, who have also unanimously approved.

Opening of Inverness Tuberculosis Dispensary.

The Inverness Tuberculosis Dispensary was formally opened on July 7th by Provost Birnie, Inverness. The treatment by tuberculin is an adjunct to the Forbes Dispensary. Provost Birnie eulogised the good work which the dispensary had done for a number of years.

Forfar Infirmary and Paying Patients.

At the quarterly meeting of the Forfar Infirmary directors it was decided, by a majority of 9 to 4, to admit paying patients to the institution. The motion was objected to on the ground that it would alter the character of the institution. There is to be no preferential class treatment, but the wealthier man, who desires to do so, can pay a weekly sum towards his treatment.

July 18th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The National Insurance Bill.

THE committee of the Irish Party, to which was committed the task of framing amendments to adapt the National Insurance Bill to the special conditions of Ireland, last week presented its report, which was adopted by the party. The most important recommendation, so far as the medical profession is concerned, is that "as regards the whole of Ireland medical benefit should be excluded from the Bill." It is stated as a reason for this that the poor of Ireland are already sufficiently supplied with medical attendance, mainly at the expense of the rates. This way of dealing with the crux of the medical question was also demanded by the meeting of medical graduates of the University of Dublin held on June 26th. It has not, however, been adopted by any other body of medical men in Ireland, and it is doubtful whether the solution proposed will be welcomed by the profession as a whole. In all its deliberations the profession has proceeded on the assumption that the principle of medical benefit would certainly apply to Ireland, and discussion was limited to the improvement of the conditions of application. The committee of the Irish Party also recommends, *inter alia*, that no persons working for their parents or other persons liable to maintain them should be compulsorily insurable; that domestic servants should be insured at a greatly reduced rate for all purposes except sickness benefit, and that the employer should be under contract to pay the wages during temporary sickness; and that the minimum limit of membership for an approved society in Ireland should be 500.

Dublin University Graduates and the Insurance Bill.

A statement has been issued by a committee of medical graduates of Trinity College, Dublin, for submission to Members of Parliament in reference to the National Insurance Bill. The committee emphasises the fact that the meeting of medical graduates held on June 26th was, with the exception of two dissentients, in favour of condemning the medical clauses of the Bill as unnecessary in, and unsuitable to the conditions of, Ireland. Discussing the amendments which would be required to permit of any successful working of the Bill, the committee observes that a wage limit of £160, such as is suggested in the Bill for certain classes of workers, would admit the great bulk of the middle class of *employed* persons in Irish country towns—i.e., the class from which Irish medical men make their living. No practicable contract fee would recoup medical men for loss of this class. In England, also, a large proportion of the medical man's private practice lies among those whose income is between £2 and (say) £4 a week. Experience shows that this class is under no hardship in providing medical attendance at their own expense without assistance of any kind. The committee suggests a limit of £2 a week in England, and in Ireland, £1 10*s.* a week in the large towns, and £1 a week in the country. This should be a *total income limit*, and not a *wage* limit, and *be applicable alike to voluntary and compulsory insurers*. Free choice of medical attendant greatly contributes to the confidence that should exist between medical man and patient, and is advisable in order to maintain a satisfactory professional relation. Moreover, if this be not permitted, the Bill threatens immediate ruin to those practitioners who are not selected for work under the Bill. Experience of the Friendly Societies shows that they are unable to appreciate either the care required by sick people or the education and skill required to give it. Their only anxiety is to cut rates as low as possible. Any extension of their activity, fortified by public subsidies and State recognition, is to be deprecated. The committee also urges that medical remuneration should be what the profession considers adequate, and that adequate medical representation should be given among the Insurance Commissioners, in the Central Advisory Committee, and in the Local Health Committees, and considers that statutory recognition should be made of a Local Medical Committee representative of the profession in the district of each Health Committee. Attention is also drawn to the injury likely to be done to voluntary hospitals, and the injustice of the compulsory clauses referring to Ireland.

Munificent Gift to the Dublin Hospitals.

In order to commemorate the first visit of King George to Dublin since his accession, Lord Iveagh has handed to His Majesty a sum of £50,000 for distribution to the hospitals of Dublin. In 1903 Lord Iveagh made a like gift in honour of the visit of King Edward. Within the last few months his lordship, who is Chancellor of the University of Dublin, presented the National University with a magnificent site for its proposed buildings.

Dinner to the Right Hon. Dr. Michael F. Cox.

A number of his friends entertained Dr. Michael F. Cox to dinner last week at the Shelbourne Hotel in honour of his

recent appointment as a member of the Privy Council in Ireland.

The Meeting of the Medico-Psychological Association of Great Britain and Ireland.

The meeting of this association was held in Dublin on July 13th and 14th, and was a highly successful occasion. Dr. W. R. Dawson was elected President for the year.

Death of an Inmate of Dundrum Criminal Lunatic Asylum.

On July 17th Mr. W. A. Rafferty, coroner for South County Dublin, held an inquest on the death of an inmate of the Dundrum Criminal Lunatic Asylum, which had resulted from an injury to the head inflicted by another inmate. Both men had committed murder prior to their admission to the institution. It was proved that at the time the injury was given no attendant was present. It was also stated that the attendants worked 16 hours a day. The jury, in finding the cause of death, exonerated the officials from blame, but added that the attendant staff was insufficient, and the hours of duty "wholly excessive."

Ulster Asylums.

At the monthly meeting of the Monaghan and Cavan Asylum, held on July 13th, a subcommittee reported in reference to a letter from the Treasury on the vexed question of the relations of Imperial and local taxation. In 1874 the total average cost per head of the patients was £20 16*s.*, which was equally divided between Imperial and local taxation, leaving £10 8*s.* for each to pay. Now the average cost per head had risen to £25 15*s.*, of which the Imperial charge was £10 8*s.*, while the local ratepayers, with a diminishing population and an increasing number of inmates, had to pay £15 7*s.* In the opinion of the subcommittee (and this was adopted by the board), the least that could be done to carry out the principle established in 1874 was that the Imperial taxation should bear the half of the £25 15*s.* In reference to the Asylum Bill, a resolution was carried calling on the Parliamentary representatives of Cavan and Monaghan to oppose that part of the Bill which reduced the hours or the duty of the officials. At a meeting of the committee of management of the Tyrone and Fermanagh Asylum held on the same day a resolution was passed protesting against the clauses in the Asylum Attendants Bill which proposed reducing the basis of asylum attendants to 60 hours per week. An interesting point arose on a statement of the medical superintendent that it frequently happened that patients were committed to the asylum who should really be sent to prison. It was decided to take the opinion of the committee's solicitors on the matter before issuing a notice to the magistrates.

The Belfast Natural History and Philosophical Society.

During the recent visit of the King to Ireland an address from the Belfast Natural History and Philosophical Society was received by him, and the President (Sir John Byers, M.D.) and the honorary secretary (Mr. R. M. Young, M.R.I.A.) were personally presented to His Majesty.

July 19th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Visitors' Tax at French Health Resorts.

A MINISTERIALLY appointed special commission has for a long time been engaged in considering the best means of developing the mineral water resources of France, and after four years of persevering effort it has induced Parliament to pass a law authorising a *taxe de séjour*. The payments under the new system will be analogous to the kur-taxe of the corresponding German and Austrian health resorts. In accordance with custom, a decree of the Council of State has recently specified the conditions under which the new law will be applicable. This decree provides that every request for the official recognition of any locality as a mineral water or climatic health resort shall be addressed to the prefect of the department, who will hold an inquiry, and if satisfied will grant the necessary authorisation. The various details relative to the tax must be duly considered by the municipal council of the commune, which will also make the claim for payment, at the same time indicating the manner in which the tax is to be paid, its amount, its duration, and the purposes to which the proceeds will be applied. As a general rule (subject, however, to the voting of the commune concerned) the days of a visitor's arrival and departure will not be counted for taxation. When the tax is based on the rental of a room or a house its amount must be placarded in the room or house. Its duration will be for a period of five years at most, unless it has been made security for an authorised loan, in which case it may continue until the loan has been paid off. The scale of charges must always be exhibited at the entrance of the *mairie* of the commune and in all hotels and furnished houses offering accommodation to persons coming from outside the commune. Hotel-keepers, lodginghouse-keepers, and landlords must have a special register, which will be supplied free of charge by the *mairie* and in these they will enter the names, ordinary places of abode, and dates of arrival of all their tenants. Hotel-keepers and lodginghouse-keepers will at the time when their bills are paid collect the tax from their tenants and give a receipt for it; the tax must, moreover, be collected on the departure of the tenant, even although the latter has made a special agreement with the landlord for deferred payment of the hotel bill. For infraction of these regulations the decree imposes a penalty of twice the amount of the tax, and when fraud is proved a penalty of thrice the amount of the tax. To recapitulate, the tax is based on the rent paid by all visitors coming from outside the commune and remaining for more than five days; all persons who accompany visitors, whether as relatives or servants, are also liable. The average charge will be very small—probably from 5 to 10 francs for each individual. It is expected that the proceeds will allow improvements to be made in many neglected mineral water stations in which property owners deriving good profits from entertainments have given more attention to these than to the mineral water establishment with its indispensable accessories, a park, public walks, dietary regulations, physical methods of treatment, and the like. At the same time it must not be forgotten that some of the municipal councillors will be certain to raise objections to the money being employed for this purpose, and the matter is one in which the councils have extensive powers, because, according to French law, the right of levying taxes belongs only to the State and the communes. As a question of politics it is inevitable that the elected members of the councils will first of all desire to conciliate their constituents so as to retain their seats, and will be under a great temptation to apply the proceeds of this tax for the benefit of the townspeople, by reducing the local rates and providing hospitals, schools, market-places, &c., with the result that improvements which might have been made in the interest of visitors, and for which their money might have been used, will remain for future consideration. There was a proposal that the proceeds of the tax should be disbursed by a commission called the Chambre d'Industrie Thermale, on which the municipal council, the proprietors of the mineral water establishment, and the local medical men should be equally represented, each of these three interested classes appointing one-third of the members, but in Parliament political considerations prevailed and the new decree assigned this duty to the municipal council. It may, therefore, be said that in this new tax the mineral water resorts possess an important instrument of development which will be serviceable or not according to the manner in which the municipal councils make use of it. In some of the councils the majority consists of hotel-keepers who immediately took advantage of the opportunity of doing away with all the town dues (*octrois*) on articles brought into the place; they could then buy provisions more cheaply than before, but they naturally did not reduce the price of their rooms. This example shows that there may well be some misgiving as to the purposes for which the new tax will be applied.

A Home for Medical Men in Reduced Circumstances and a Proposed Medical Hotel.

Some undertakings for the benefit of the profession are gradually undergoing an interesting development. A year ago a boarding house was opened in the neighbourhood of Paris where medical men in reduced circumstances or bad health are received at a very moderate charge, and it is rapidly becoming prosperous in consequence of the gifts and bequests which it receives; the proceeds of the concerts given by the medical orchestra (several times

mentioned in this column) are also made over to it. Another enterprise of interest to the profession has been suggested by Dr. Tourtourat, general secretary of the syndicate of medical men of the Seine. His proposal is that there should be established in Paris a hotel for the exclusive use of medical men. The bedrooms would be reserved for medical visitors from the provinces or abroad. The rooms on the ground-floor would be available for meetings of syndicates, committees, and learned societies, or for any meetings having a scientific and professional object. The income would be derived from the medical societies concerned and from other sources. The proposal has received very favourable consideration from the medical societies and may perhaps become an actual fact some day.

Les Voyages d'Études Médicales.

The eleventh Voyage d'Études Médicales, under the actual presidency of Professor Landouzy, will take place in the South-East of France from August 28th to Sept. 11th, when the following route will be observed: Vals, Montmirail, Balaruc-les-Bains, Lamalou, Alet, La Fou-Saint-Paul-de-Fenouillet, Prats-de-Mollo, La Presle, Amélie-les-Bains, Le Boulou, Banyuls-sur-Mer, Molitg, Le Vernet, Thuès, Mont-Louis, Font-Romeu, Les Escaldes, Ax-les-Thermes, Ussat, Aulus, Salies-du-Salat. A half-fare will be granted on all French railways from the station of arrival on French territory to the place of assembly, Lyons, and again from the place of disbanding, Toulouse, to the same point. The total cost of the trip from Lyons to Toulouse, including first-class fare, conveyances, hotels, board, baggage, and "tips," will be £14. For further particulars application should be made to Dr. Carron de la Carrière, 2, Rue Lincoln, or Dr. Jouaust, 4, Rue Frédéric-Bastiat, Paris.

July 17th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Reform of the Workmen's Insurance Laws.

THE work of reforming the workmen's insurance laws has now come to an end, the Act having been passed before the Parliamentary vacation. As already explained in THE LANCET of Sept. 4th, 1909, the new law is not a complete alteration of the existing workmen's insurance law, but rather a consolidation of the various laws and regulations concerning sickness, accidents, old age, and invalidity, with an extension of their application. The original form of the Bill, called Reichs-Versicherungs-Ordnung, was extensively amended before its final passing. The first scheme of the year 1909, a description of which may be found in THE LANCET (1909, Vol. II., p. 754), met with general opposition from the sick clubs, from the employers' associations, and especially from the medical profession, so that it was remodelled by the Home Office. The Bill in this modified form, after having passed the Federal Council, was introduced in Parliament in May, 1910; and after the first reading was referred to a committee of the House. That committee was busy from June, 1910, to Easter, 1911, in discussing and amending the Bill, and was even by a special law empowered to sit during the Parliamentary vacation. The work of that committee was so thoroughly done that the second and third readings in the House were completed in a few weeks, the Bill having become an Act before the close of the session at Whitsuntide. The Act is of gigantic dimensions, containing not less than 1805 paragraphs; according to the daily newspapers it is exceeded in length only by the codification of the civil law which was made some ten years ago. The Act provides for the institution of an elaborate system of insurance offices; there will be local insurance offices for each city and rural area, district insurance offices for each district, and the Imperial Insurance Office already existing for the whole Empire. It is the duty of these offices to supervise and control the organisations to which as hitherto the actual insuring is intrusted—namely, sick clubs, employers' associations, and old age and invalidity insurance institutions. The constitution of those bodies has been left practically unchanged, an exception being made only in the case of the sick clubs, which were said by the Government authorities to have become mere social democratic organisations whose salaried officials, such as clerks and treasurers, were almost always recognised members of the Social Democratic party. With a view to prevent a continuance of this system the sick clubs are to be more strictly controlled than heretofore. Instead of sick clubs for every trade there will be one general sick club for each town or rural area, but the existing trade sick clubs will be allowed to continue if the number of members is at least 1000. In this way a good many small sick clubs will be broken up, whilst the formation of new trade sick clubs is henceforth prohibited. Similar provisions concern the existing factory sick clubs (Fabrik-Krankenkassen), which admit only the workmen of a single factory. Insurance against sickness will henceforth be compulsory for agricultural labourers and for domestic servants, who have hitherto been excepted from the operations of the insurance law. Special clubs, called country sick clubs, will be instituted for these classes, their principal feature being that they have no self-government at all but are managed by the local authority. There was one clause adopted during the third reading of the Bill in the House which will have an important bearing on medical practice, especially in the country. It is to the effect that insurance shall be compulsory for employed persons earning not more than 2500 marks (£125) per annum. By this provision a good many people in the country, where incomes are often under the above sum, will henceforth belong to clubs and will receive medical attendance accordingly. On the other hand, the clubs are expressly prohibited from allowing members to continue their membership when they become employers and have an income of more than 4000 marks (£200) per annum. With regard to medical attendance, a certain improvement is made by a provision stating that only qualified medical men may be admitted to club practice; the abuse existing in certain clubs of allowing attendance by notorious quacks will thus be abolished. This is one of the few favourable points of the law; but the principal wish of the great majority of the profession that free choice of a medical attendant should be made compulsory has not met the approval of the legislature. There are but few paragraphs of the law dealing with the question of club practice; there must be written contracts between the clubs and their medical men, but the particulars of the contracts are in all respects left to be settled by mutual agreement, so that the clubs are at liberty either to appoint a certain number of medical men or to introduce the free-choice system. The law provides only that there may be a choice for the members between at least two medical men. Nothing has been left in the new law of the highly objectionable provisions of the original scheme instituting arbitration courts with power to compel a medical man to retain a club appointment even in the case of a disagreement and to fine him for disobedience. The Government and Parliament were, in the course of the debates, convinced that it was not desirable for patients to be attended by a medical man working under compulsion and only *pro formâ* to avoid a fine. If no agreement has been entered into, the committee of the club will be authorised to pay the members a certain sum over the usual sick-pay and to leave it to them to consult a medical man as private patients. The law has satisfied neither the profession nor the sick clubs. It is very likely that local medical strikes will frequently take place, although a general strike of the profession is not probable. At the last meeting of the Medical Union in Stuttgart, where 23,625 medical men were represented, a resolution was unanimously adopted to the effect that the medical profession represented by the Medical Union was very much disappointed in the new law, and had no longer any confidence that their grievances will be considered by Parliament. The committee of the Union will open a central office for the consideration of every contract between a sick club and members of the Union; members are pledged not to agree to any contract without the assent of the Union. Contracts will be approved by the Union only when they do not hinder the introduction of the free-choice system, and when the fees are in accordance with the work. Club members earning more than 2000 marks per annum will not be entitled to attendance at the reduced fees of ordinary club patients, but the club will have to pay for them the fees of private patients. The local committees will send the contracts to the above office and the members are also requested not to renew existing contracts without giving previous notice to the office. The above resolution will certainly inaugurate an era of severe struggles and conflicts. This is also the opinion of the

Association of Sick Clubs as expressed at its recent meeting, where the attitude of the medical profession was very much blamed.

A Medical Orchestra.

Following the example of their professional brethren in Paris the Berlin medical men have recently founded an orchestral society which has been so well supported that at the inaugural meeting 60 medical men were present as members. It has been decided that wives and daughters of medical men may also be admitted to membership, and it is hoped to have all the instruments played by amateur performers sufficiently accomplished to make the engaging of professional musicians unnecessary. Dr. Pollak, well known both as an ophthalmic surgeon and also as a musician, will act as conductor, and Dr. Joachim, editor of the *Berliner Aerzte Correspondenz*, will be the general manager. Concerts are to be given for the benefit of medical benevolent funds.

July 17th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Pasteur Institute, Kasauli.

THE work done at this institute since August, 1900—the date of its inauguration—is the subject of a report by its director, Major W. F. Harvey, I.M.S. In all, 11,305 cases have been treated since the above date with satisfactory results, there being only four failures of the treatment. In 1910 the number treated amounted to 2073, as against 1937 for 1909.

Annual Indian Medical Service Dinner at Simla.

The annual dinner of the Indian Medical Service took place on June 19th, when Surgeon-General C. P. Lukis, I.M.S., presided, and in all 38 sat down.

Calcutta.

Calcutta is still perturbed about its water-supply. Muddy water has been passing through the new pipes, and a committee of inquiry has been appointed to find out the cause. The Calcutta corporation has decided to give a piece of land for a wing of a hospital in commemoration of the late King.

School of Tropical Medicine and Practice.

The scheme for the establishment of the above school at Calcutta is more or less mature, and it is hoped to have the first course of instruction for post-graduates started this cold weather. The scheme was put forth by Surgeon-General Lukis. He has also recently spoken in the Legislative Council in favour of an independent medical service. There is no doubt that the time has come for a definite pronouncement from Lord Morley on the subject. Schools of medicine are putting out graduates in medicine every year, and the question is what is to become of them.

June 24th.

Obituary.

THOMAS LAW WEBB, M.D., B.CH. BIRM., M.R.C.S. ENG., L.R.C.P. LOND.

ON July 3rd there passed away at Weston-super-Mare Dr. T. Law Webb, of Ironbridge, Shropshire, who was in many respects one of the most noteworthy general practitioners in the Midland counties.

Thomas Law Webb was born in Ironbridge in 1846, and commenced his medical life as apprentice to his father at the age of 17. Three years later he entered Sydenham College, Birmingham. He took the M.R.C.S. in 1870 and the L.R.C.P. in 1872. He lived practically all his life in the place where his father and his grandfather had lived as medical men before him, joining his father as partner and eventually taking over the practice. The district gradually altered in social position and the work in consequence became harder and less remunerative, yet for more than 40 years he devoted himself to the study of medical science, and especially of pathology, with an enthusiasm which never faltered. During the early years of practice he studied anatomy and physiology, and he passed the first F.R.C.S., no mean feat for a busy practitioner. He taught himself German in order that he might keep in touch with advanced thought in his special subjects, and often corresponded with German writers. After days spent in laborious work he would spend his evenings with the microscope perusing the developments of pathology. He chiefly worked at the diseases of the blood and the protozoal diseases in man and animals, on both of which he became a recognised authority, but he was profoundly interested in the etiology of cancer. He wrote many valuable papers on these subjects, which were published in our columns, in those of the *British Medical Journal*, and in the *Birmingham Medical Review*, of which he was for a time one of the joint editors. His best known work was that on "Cancer Houses," founded on observations made in his own registration sub-district of Madeley, and extending over a period of some 60 years. His final work on this subject he did not live to publish, but his complete statistics brought up to date, together with careful maps of the observed area, showing the marked houses, are now in the best possible hands, and it is hoped they may yet be of service. At first unaided and unrecognised, he worked in his little laboratory far from any intellectual or scientific centre, far from his fellow workers, and unhelped by any meed of appreciation from those around him, but his zeal never abated and his keenness never became blunted. Later in life his work and character began to be appreciated. In 1897 the title of Associate of Mason's College, Birmingham, was conferred upon him. In 1901 the newly founded University of Birmingham conferred upon him the honorary degrees of M.B. and Ch.B., a mark of recognition which gave him the greatest pleasure. In 1903 he was awarded the degree of M.D. for his thesis on "The Etiology of Cancer with Special Reference to Cancer Houses." In 1897 he founded the Clinical and Pathological Section of the Shropshire and Mid-Wales Branch of the British Medical Association, and year after year he was elected its chairman, and later he was president. In 1898 he was elected a member of the committee appointed by the Birmingham Branch for the investigation of local conditions affecting malignant disease. In the same year he was appointed honorary pathologist to the Salop Infirmary and soon after to the Shrewsbury Eye, Ear, and Throat Hospital. He continued to hold these posts, which were created for him, until the present year.

To the bare facts of Dr. Law Webb's life we are able to add a brief appreciation by a personal friend. "Of fine presence he was one of whom his professional brethren felt proud, a single-minded man who followed the highest ideals both in his life and in his practice. His mind retained to the last the freshness of youth, and there was nothing he liked better than to attract young medical men around him and inspire him with his own enthusiasm. His home was a very happy one and a centre for high thinking and high ideals in his own little town. He himself was a charming host, a man with wide human sympathies, a quiet fund of humour, and an unfailing store of quaint old-world sayings and old-world stories. Water-colour sketching and astronomy were his principal hobbies, and he studied the stars through a telescope of his own making. I have often heard it regretted that he did not live in some university town where his gifts and his work would have been better appreciated; but it may well be that lives such as his, lived simply and quietly out of the world's sight, 'still loftier than the world suspects,' do much to raise and ennoble the profession of medicine."

Dr. Webb had long looked forward to retiring from practice and devoting himself to cancer research, and he patiently accumulated stores of observation and knowledge with this end in view, but the pay was too poor and the work, especially his contract work as a colliery surgeon, was too hard for him. When at last he retired from general practice he was a worn-out man, and the task, even though it was a labour of love, was impossible for him.

He died from cerebral hæmorrhage and was buried in the beautiful cemetery on the hill overlooking the town and bay of Weston-super-Mare. He was a brother of Captain Webb, the famous swimmer of the English Channel. He leaves a wife and daughter and two sons.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Corrado Bernabei, professor of internal

pathology in the Siena School of Medicine.—Dr. W. Blackburn, professor of pathological anatomy in the Georgetown University School of Medicine, Washington.—Dr. Charles H. Dixon, lecturer on surgery in Washington University, St. Louis.—Dr. Gregorio Manca, professor of physiology in the Sassari School of Medicine.—Dr. Rudolf Albrecht Koehler, surgeon-general in the Prussian army and for some years professor of military surgery in the Kaiser Wilhelm's Academy. He was from 1874 to 1883 assistant to Professor v. Bardeleben in the Surgical Clinic of the Charité. His name should not be confounded with that of his junior namesake, Surgeon-General Albert Koehler, who succeeded him in the Charité and also at the Kaiser Wilhelm's Academy. —Professor A. Mitscherlich, a well-known Berlin surgeon. He was the son of the eminent Heidelberg chemist, Professor Eilhard Mitscherlich, and was for many years assistant to Professor Langenbeck. He was 79 years of age. His published works dealt with various surgical subjects, also with cocoa and chocolate as foods, and with alcohol poisoning.—Dr. Hans Leyden, nephew of the eminent professor, has died in Berlin from septic infection. He was for many years in practice amongst the foreign residents in Madrid.

THE NATIONAL INSURANCE BILL.

OUR readers will certainly have followed the progress of the Bill in Committee, while our Parliamentary correspondent continues to supply a summary of the principal events as they may affect the medical profession.

On Wednesday in last week progress was reported while the subject of sickness benefit (Clause 8) was under discussion. A highly interesting debate was originated by an amendment proposed by Mr. Austen Chamberlain to exclude treatment in sanatoriums from the sickness benefits on the grounds that such treatment was not really the ordinary work of insurance against sickness. A speech by Dr. Addison made clear to the House the logical grounds on which the treatment of tuberculosis in sanatoriums is founded and showed that from the great drain on the funds of the provident societies made by their tuberculous subscribers, to use his words, "it will be nothing less than a national calamity were this clause to be deleted from the Bill." Dr. Esmonde, Dr. Chapple, and Dr. Hillier made interesting contributions to the debate, the last-named shrewdly pointing out that to provide sanatorium treatment merely for the insured would not check the spread of phthisis in the home. The Chancellor of the Exchequer suggested that later on it might be found possible to extend sanatorium benefits to the dependents of the insured, and Mr. Austen Chamberlain withdrew his amendment, understanding that to some extent the use of sanatoriums was the subject of a large experiment.

On Monday, July 17th, progress was made with the Bill when Sir A. Griffith-Boscawen moved an amendment to Clause 8 (1) *e*, which deals with the maternity benefit, to grant medical benefit also to the women entitled to maternity benefit. Mr. Lloyd George could not accept the amendment, but later moved an amendment providing that a wife who worked and was insured should receive sick pay of 7*s*. 6*d*. a week as well as maternity benefit. The amendment was accepted, and is a very large concession to the general feeling that the maternity benefit was inadequate if it was to prove the source of racial security aimed at. On Tuesday Clause 8 and on Wednesday Clauses 9 and 10 were definitely finished with.

The following memorial, to be sent to the Chancellor of the Exchequer, is being signed by members of the House of Commons:—

We, the undersigned Members of Parliament, respectfully urge upon the Chancellor of the Exchequer the desirability of amending, where necessary, the National Insurance Bill, so as to include the following provisions:—

(1) That there should be a schedule for medicines and medical appliances of prices approved by the Insurance Commissioners for each district, and that insured persons at their own choice shall be empowered to take their prescriptions and orders for drugs and appliances forming part of the medical benefit to any person, firm, or corporate body lawfully entitled to carry on the business of a dispensing chemist, provided that such person, firm, or corporate body is willing to supply the medicines, &c., at the schedule price.

(2) That medicines for the insured should be dispensed by or under the direct supervision of a qualified pharmacist.

(3) That there should be representation of pharmacy on the various advising and administering bodies.

(4) That the administration of medical benefit may be in the hands of the Health Committees rather than those of the friendly societies.

THE GENERAL MEDICAL COUNCIL AND THE BILL.

The President of the General Medical Council, Sir Donald MacAlister, has addressed the following important communication to Mr. Lloyd George:—

299, Oxford-street, London, W., July 12th, 1911.

The Right Honourable the Chancellor of the Exchequer.

DEAR SIR,—With reference to your letter of June 13th, the Committee of the General Medical Council desire me to express their acknowledgments for your courteous reply to the communication concerning the National Insurance Bill which was addressed to you on behalf of the Council. The committee recognise fully the value of the assurances you have given of your personal agreement with a number of the Council's recommendations; but they deem it their duty to urge the necessity of introducing into the Bill certain explicit amendments for the purpose of giving legislative effect to the intentions and desires you express.

I am accordingly instructed to invite your favourable consideration to the following suggestions and explanations, and to inquire whether amendments in the sense indicated will be proposed in Parliament at the instance of the Government. The headings refer to those of your reply and of the Council's report.

1 (*a*). *Insurance Commissioners.*—Following the wording of Clause 43 (5) of the Bill, add at the end of Clause 41 (1) the words: ", but so that one at least of the Commissioners so appointed shall be a duly qualified medical practitioner."

1 (*b*). *Advisory Committee.*—In Clause 42, after the words "consisting of," insert the words "duly qualified medical practitioners."

1 (c). *Local Health Committees.*—Under Clause 42 (5), it may happen that not more than two medical practitioners are appointed on a Health Committee of twenty-two. Having regard to the important functions of the committee in relation to "medical benefit," it appears desirable that provision for a more adequate representation should be made.

2. *Approved societies.*—From facts within its knowledge, some of which are set forth in the reports enclosed herewith for your information, the Council is convinced that the conditions of practice under the control of various associations, which purport to supply "medical aid" to the public, are in general adverse to the highest efficiency of the practitioners employed, and therefore to the welfare of their patients.

The Council thinks it imperative in the public interest that these conditions should not be reproduced in a national scheme for the administration of "medical benefit." It must therefore press strongly for an amendment of Clause 14, which will have the effect of placing such administration under the exclusive control of the Local Health Committees and the Insurance Commissioners. Thus in Clause 13 (1), lines 25, 26, the words "and, subject ..... medical benefit," and in Clause 14 (1) the words "approved society and" should be deleted.

As regards "maternity benefit," the committee understand from your reply that this is not considered to be of the nature of "medical benefit," but rather as a form of "sickness benefit," applicable to the case of a woman disabled from her ordinary employment on account of her confinement. If this view is correct, the committee fail to see that any provision is made for the attendance of a medical practitioner or midwife at and after confinement in the case of an insured woman. Clause 8 (6) excludes the recipient of "maternity benefit" not only from "sickness benefit" but from "medical benefit."

Referring to paragraph 7 of your reply, "maternity benefit" is there treated as equivalent to "sickness benefit in times of confinement"; or in the words of Clause 8 (*c*) it is a payment of *thirty shillings* to insured women "whilst rendered unfit to provide their own maintenance" during four weeks after childbirth. Some form of "medical treatment and attendance" must clearly be provided as well as ordinary maintenance in such cases. It appears therefore to follow that in Clause 8 (6), to which you refer us, the words "or medical benefit" should be deleted.

3. The committee desire to be assured that in making "arrangements" with duly qualified medical practitioners under Clause 14 (1) the Local Health Committees will have instructions, subject in each case to the approval of the Insurance Commissioners, (1) to form a panel, including all practitioners of good standing who are willing to act within a given district; (2) to allow an insured person to choose (say annually) the practitioner on the panel who is to attend him; (3) to provide specially (e.g., by an arrangement with a hospital, as hereinafter suggested) for consultations or serious operations where these are necessary; (4) to provide specially for the treatment of maternity cases, whether attended by a practitioner or a midwife.

In order to make it clearer that the "arrangements" in question shall be submitted to the Insurance Commissioners before they are confirmed, the committee desire that Clause 14 (1) should be altered so as to read as follows: "For the purpose of administering medical benefit every Local Health Committee shall, subject to the approval of the Insurance Commissioners, make arrangements with duly qualified medical practitioners for insured persons to receive attendance and treatment from such practitioners."

The committee agree with you as to the exclusion of members of the profession who may show themselves unfit for the performance of a very responsible public duty; and they would point out that the Council takes a grave view of such misconduct, and is accustomed to exercise its disciplinary authority in cases of the kind.

4. The resources of voluntary hospitals are likely to be diminished by the operation of the National Insurance Scheme. Many of them depend largely on regular contributions from employers and from workmen. There is reason to apprehend that, in view of the weekly insurance payments to be made by both classes, these regular contributions may cease to be paid to the hospitals; they will in large measure be diverted to the Insurance Fund. On the other hand, the demand on the hospitals—for the highly skilled treatment provided in their wards by means of the gratuitous service of eminent physicians and surgeons, for the trained nursing that is necessary in cases of grave illness or operation, and for the provision of costly appliances and apparatus—will remain as at present. In many cases the "domiciliary treatment" of insured persons must be supplemented by treatment in the hospital ward if they are to have a fair chance of recovering their health and resuming their payments to the Insurance Fund.

In Clause 15 provision is made whereby Local Health Committees

may make arrangements, to the satisfaction of the Insurance Commissioners, for subsidising sanatoria or other similar institutions, apparently on the ground that such institutions have a claim on the fund in respect of the treatment therein of insured persons. In the view of the Council the voluntary hospitals have the same claim, and should be dealt with in the same manner. Under Clause 17 it is left to an "approved society" "to grant such subscriptions and donations as it may think fit to hospitals and other charitable institutions." The society may impose such conditions in respect of its subscription or donation as it thinks fit, but no reference of the conditions to the Insurance Commissioners is prescribed. The service rendered by the voluntary hospitals concerns the whole population, insured and uninsured, and the Council is apprehensive that their efficiency may be impaired, if they are constrained for financial reasons to accept the conditions laid down by "approved societies," subject to no review by the Insurance Commissioners or the Advisory Committee.

In Clause 12 (1) the "sickness disablement or maternity benefit" of an insured person without dependents, who is an inmate of a hospital supported by charity, is paid to the Local Health Committee—not to the hospital in which the patient receives both maintenance and medical benefit. If the insured person is in a sanatorium the Local Health Committee makes an "arrangement" with the institution to meet the cost: if the person is in a hospital it makes no such "arrangement." The result may be that a hospital, whose funds are already depleted owing to the establishment of the Insurance Fund, may at the same time be called on to bear the expense of "benefits" which the Insurance Fund has undertaken to provide.

The Council is strongly of opinion that in the interest not of the insured alone, but of the whole community, which is largely indebted to the voluntary hospitals for the training of medical men and for the improvement of medical knowledge and skill, it is both equitable and prudent to minimise the danger to which these institutions are exposed under the present provisions of the Bill. They should therefore be included under a clause similar to Clause 15 (1), and if need be omitted from Clause 17 as it stands. The Local Health Committees should, in other words, be empowered to make arrangements, to the satisfaction of the Insurance Commissioners, with hospitals for the treatment of insured persons therein. As regards the question of the inspection and approval of voluntary hospitals, which is alluded to in your reply, it may be pointed out that the administrators of the Hospital Sunday, King Edward, and other similar Funds throughout the country, take steps to satisfy themselves of the efficiency of the institutions to which they make grants, and that no well-conducted hospital objects to visitation and inspection by competent persons for such a purpose.

5. On the assumption that the administration of "medical benefit" is to be in the hands of the Local Health Committees, the purpose of the Council under this heading would be fulfilled if the first sentence of Clause 14 (1) were altered so as to read as follows: "Every committee shall also, subject to the approval of the Insurance Commissioners, make arrangements with duly qualified pharmacists for the supply of proper and sufficient drugs and medicines and surgical requisites to insured persons."

Seeing that injuries, accidents, and surgical disorders are as likely to disable the insured as affections requiring treatment by drugs alone, it seems obvious that provision should be made for the supply of the ordinary materials that are necessary in such cases. By entrusting the supply and dispensing of medicines, &c., to qualified pharmacists, who are subject to the provisions of the Pharmacy Acts, the maintenance of official standards of quality and purity would be ensured.

6 and 7. The points raised under these headings have already been dealt with above.

8. The committee recognise that the conditions in Ireland differ in certain respects from those in England and Wales and in Scotland. But they are satisfied that the general considerations which they have ventured to lay before you in the foregoing paragraphs are no less applicable to Ireland than to the rest of the United Kingdom. In the case both of "deposit contributors" and of other insured persons, it is eminently desirable that a panel, consisting of practitioners who are willing to act, should be provided in Ireland as elsewhere, and that the medical service of the insured should be distinguished from the medical service under the Poor-law.

I am, yours very faithfully,
DONALD MACALISTER, President.

The following is the reply received from the Chancellor of the Exchequer:—

Treasury Chambers, Whitehall, S.W., July 13th, 1911.

DEAR SIR,—I am desired by the Chancellor of the Exchequer to acknowledge the receipt of your letter of the 12th instant on behalf of the Committee of the General Medical Council, offering suggestions for the amendment of the National Insurance Bill, which shall receive careful consideration. Yours faithfully,

Principal Sir Donald MacAlister, K.C.B. R. G. HAWTREY.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE BILL.

A meeting of the College was held on Thursday, July 13th, and the following statement has been sent to us for publication:—

RESOLUTIONS AND RECOMMENDATIONS OF THE COLLEGE RELATING TO THE NATIONAL INSURANCE BILL.

These fall under the headings of: 1. Contract practice. 2. The representation of the medical profession upon the boards administering the Act. 3. The administration of medical and maternity benefits. 4. Limitation of the income of those entitled to medical benefit. 5. The choice of doctor. 6. The dispensing of medicines. 7. Special medical services. 8. Disease or disablement caused by misconduct. 9. Sanatorium benefits. 10. Powers and duties of Local Health Committees.[1]

1. *Contract practice.*—The College views with great apprehension the prospect that all medical treatment of insured persons under this Bill should be based entirely upon the contract system, and passed the following resolution:—

"The Royal College of Physicians is of opinion that a system of per capita contract practice among the industrial classes, if it should become universal, as appears to be contemplated throughout the working clauses of the National Insurance Bill, will lower the standard of medical practice, and will prove in this way injurious to the public and to the profession."

2. *The representation of the medical profession upon boards administering the Act.*—Alterations should be made providing that not less than one-fourth of the Insurance Commissioners shall be registered under the Medical Act; that the profession shall be represented upon the Advisory Committee; and that the medical practitioners upon the panel in each district shall be represented upon the Local Health Committee by not less than two registered practitioners.

3. *The administration of medical and maternity benefits.*—These benefits should be administered by the Local Health Committees and not by approved societies.

4. *Limitation of the income of those entitled to medical benefit.*—A clause should be added providing that:—No insured person shall be entitled to medical benefit who is in receipt of an income larger than that which shall appear just to the Local Health Committee. Also that *voluntary* contributors having an annual income larger than that which would entitle *employed* contributors employed otherwise than by manual labour to the receipt of medical benefits shall not receive such benefits.

5. *The choice of doctor.*—The following clause should be substituted for the first part of the clause of the Bill dealing with the administration of medical benefits:—"Every Local Health Committee shall for the purpose of administering medical benefits make, to the satisfaction of the Insurance Commissioners, arrangements for each insured person to receive attendance and treatment from a registered medical practitioner, selected by the insured person from a list of registered medical practitioners approved by the Local Health Committee, subject to the consent of the practitioner selected." The local panel of practitioners shall be open to all registered medical practitioners in the prescribed area who apply to be placed upon it.

6. *The dispensing of medicines.*—Provision should be made that the Insurance Commissioners shall sanction the dispensing of medicines by medical practitioners in towns, as well as in the country, when the circumstances are such as to make it expedient to do so; for the supply of proper surgical dressings and appliances; that steps should be taken to ensure that the drugs and medicines are of the standard required by the British Pharmacopœia; that in all cases the dispensing of prescriptions is carried out by qualified persons; for the supply of drugs and appliances needed in case of emergency.

7. *Special medical services.*—The existing schedule for extra payments under the Poor-law is so extremely scanty that it hardly affords any guide for drawing up one for the remuneration of doctors under the Insurance Bill. The only fees specifically allowed under the Poor-law are those for fractures and dislocations of the limbs, strangulated hernia, and amputations. Upon consideration the College is of opinion that the schedule for special medical services should be framed by the Advisory Committees and the Local Health Committees, the varying nature of the conditions under which services requiring special payment would have to be performed rendering it difficult, if not impossible, to draw up a schedule which would be equally applicable to all districts. Operations, the treatment of cases requiring several visits in the 24 hours, examination of persons for certification as insane, consultations and similar special services, should obviously be specially paid for. In whatever form payment is made it appears only just and right that in addition the distance that the medical man has to go should be considered, and that an allowance be made for each mile which has to be travelled, as is now done in the case of public vaccinators under the Poor-law.

8. *Disease or disablement caused by misconduct.*—These cases, which must be included in any scheme of State insurance, are not at the present time usually admitted to club benefits. It is necessary, therefore, that the general medical remuneration should be higher if they are to be included.

9. *Sanatorium benefit.*—In regard to tuberculous disease, the National Insurance Bill in its present form provides for only a limited class of cases, and a large proportion cannot be dealt with by what is described as "sanatorium" treatment. The College is aware that the Bill also provides for other than tuberculous patients, but the conditions sought for are specially applicable to the latter, which need therefore only be considered here. To make the Bill effective provision would have to be made for the following classes of cases:—

CLASS I. (cases suitable for "sanatorium" treatment proper).—(*a*) Closed tuberculosis, in which bones or glands or internal organs are involved. (Cases requiring surgical treatment would probably be temporarily received into hospitals.) (*b*) Early and incipient cases of pulmonary tuberculosis capable of improvement or arrest. (*c*) Certain other cases that would derive temporary benefit from hygienic instruction.

CLASS II.—Under "Sanatorium Benefits" other arrangements should be included for such cases as are unsuitable for more formal institutions—e.g.: (*a*) Many village cases of more advanced pulmonary tuberculosis which might be dealt with in cheap shelters or in well-adapted shelter homes, and many cases in towns which would be unavoidably confined to their own homes. In either case properly secured sanitary, nursing, and medical supervision would be necessary, the continuance of benefits to depend on the continued obedience to the instructions of doctors and nurses. (*b*) In special homes for advanced cases. Or (*c*) In properly adapted portions of already existing institutions for advanced cases.

CLASS III.—Special or general hospitals will receive certain early and acute cases for purposes of diagnosis and treatment, previous to their being drafted into one or other of the above institutions. If these recommendations are accepted it follows that "sanatorium benefits" should be enlarged to include the provision of shelters and other requirements for the hygienic treatment of cases of pulmonary tuberculosis outside any special institution, and should also be extended to include sick allowance for cases treated in other places than in sanatoria, provided certain hygienic conditions laid down are observed. The clauses of the Bill concerned, viz: § 8. 1 (b); § 12. 1 and 2; § 13. 1, and § 15. 1, should be amended in the above sense. § 8. 1 (b) should be amended to include the treatment in sanatoria of cases suffering from tuberculosis likely to recover, or from such other diseases as the Local Government Board with the approval of the Treasury may appoint;

[1] The resolutions and recommendations are given here in relation to their subject-matter. Marginal references were added to the clauses of the Bill where such definite reference was possible. Specific amendments to these clauses are given in the form of an appendix.

and the treatment of patients suffering from advanced pulmonary tuberculosis in other institutions and places (in this Act called Sanatorium Benefit).

The College draws attention to the great importance of keeping the medical practitioner throughout the country interested in and in educational touch with the clinical aspects, diagnosis, and treatment of tuberculous disease. With this object in view the College advises: (i.) That all village group shelters and all other sanatorium treatment, except in the larger institutions connected with counties, cities, or large boroughs, should be medically administered by practitioners selected from the district in which such sanatoria are situated or in which advanced cases included under Class II. reside; (ii.) that the clinical laboratories of health departments for diagnosis, &c., should be within touch of all local institutions; (iii.) that research should be confined to a few special central hospitals, or to large sanatoria attached to counties, cities, or boroughs; and (iv.) that information with regard to the most recent advances in treatment, diagnosis, and pathology should be distributed from such research centre to each sanatorium, practitioner, or medical officer.

The College is of opinion that special remuneration will be required for the attendance of medical men upon these cases and for the additional district and institutional nurses requisite.

10. *The powers and duties of Local Health Committees* require to be more definitely described in order that that they should not clash with (those of) the existing sanitary authorities.

The following are the actual amendments of the Clauses of the National Insurance Bill recommended by the College and issued as an appendix to the paper headed Resolutions and Recommendations of the College relating to the National Insurance Bill:—

Page 2.—Clause 1, after line 20, insert "provided also that Voluntary Contributors having an annual income larger than that which would entitle Employed Contributors employed otherwise than by way of manual labour to the receipt of medical benefits, shall not receive such benefits."

Page 6.—Clause 8, line 4. In connexion with this portion of Clause 8 schedules for special medical services not mentioned in the Bill should be provided by the Local Health Committees.

Page 13.—Clause 13, line 25, delete from "and" to "benefit," line 26. The object of the omission of these words is to prevent an approved society administering medical benefits. Line 29, the words "medical, maternity and" should be inserted before the word "sanatorium," and "s" added to "benefit."

Page 14.—Clause 13. Note to be appended to line 26. Altered as in Section (8) of full Report.

Page 14.—Clause 14, line 32 to read as follows:—Every Local Health Committee shall for the purpose of administering medical benefits, make to the satisfaction of the Insurance Commissioners, arrangements for each insured person to receive attendance and treatment from a registered medical practitioner selected by the insured person from a list of registered medical practitioners approved by the Local Health Committee, subject to the consent of the practitioner selected. The local panel of practitioners shall be open to all registered medical practitioners who apply to be placed upon it. Line 37, omit the words "society or" after "such."

Page 15.—Clause 14, line 3, omit the words "situate in a rural district." Line 4, add "due provision being made as to drugs and appliances needed in cases of emergency." The object of these alterations is to enable practitioners to dispense their own medicine, if it is from any cause desirable for them to do so, and to provide for emergencies.

Page 15.—Line 5 to 15. Omitted if Clause 14, Sections 1 and 2 are satisfactorily amended.

Page 16.—Clause 16, line 17, omit "the" to end of line 18.

Page 16.—Line 21, omit from "by" to end of line 22. The object of the omission of these words is to prevent an approved society administering maternity benefits.

Page 19.—Clause 21, line 8, after "benefits" insert the words "other than medical and maternity." Line 28, the same words to be inserted after "benefits."

Page 35.—Clause 41, line 16, after "Commissioners" insert "of whom not less than one-fourth shall be registered under the Medical Act."

Page 36.—Clause 42, line 3, after "societies" insert "of the medical profession." This is to ensure the presence of registered medical practitioners on the Insurance Commission and the Advisory Committee.

Page 37.—Clause 43, line 11, for "duly qualified" read "registered." Line 12, after "Practitioners" insert "nominated by the panel."

Page 37.—Clause 44: The powers and duties of the Local Health Committees require to be more definitely described in order that they should not clash with the existing Sanitary Authorities.

THE ROYAL COLLEGE OF SURGEONS OF EDINBURGH AND THE BILL.

A memorandum has been prepared on the Bill by a committee of the Royal College of Surgeons of Edinburgh, and has been sent to all Members of Parliament. It is signed by the President, Dr. George A. Berry, and the secretary, Dr. R. McKenzie Johnston. The memorandum sets out the amendments to the Bill demanded by the medical profession, and points out that this is the third occasion on which the College has felt it to be its duty to press for delay in this very important piece of legislation. The memorandum then proceeds:—

It must be obvious that the medical benefits cannot be satisfactorily provided without the cordial coöperation of a large body of medical men. In spite of this admitted fact the Bill was drafted and presented to Parliament without any conference with those who are materially affected by it and who have the widest knowledge of what is required. It has too readily been assumed that the scheme for medical benefits proposed by the Bill is the one and only possible method by which an effective medical service can be provided. The profession is practically unanimous in holding that the amendments mentioned are essential to the present Bill as it stands, but it should be clearly understood that, even if such emendations were accepted *in toto*, a large proportion of the profession would still regard the Bill as an oppressive measure interfering with the professional life and freedom of the medical practitioner in a way in which no other profession is interfered with. It is therefore desirable that, if the Bill as a whole cannot be delayed, *the medical benefit part should be withdrawn*. A well-matured scheme could then be produced next session after consultation with the profession which has the widest knowledge of the conditions of life among the poor during sickness.

The memorandum stipulates that the medical member of the Insurance Commission should not hold office for longer than 10 years, as otherwise he would tend to lose touch with professional work. The whole document is in line with our views many times expressed. The willingness of medical men to accept a position concerning which they have never been consulted has been taken for granted, and now that their willingness is found not to exist a strong argument for delay is furnished.

KING EDWARD'S HOSPITAL FUND FOR LONDON AND THE BILL.

The Executive Committee of King Edward's Hospital Fund for London recently appointed a subcommittee to inquire into the probable effect of the National Insurance Bill upon the hospitals receiving grants from the Fund. The subcommittee ascertained the views of 32 of the principal London hospitals and drew up a report thereon. Upon receiving this report the Executive Committee agreed upon the following statement which represents an abstract of the views of these hospitals or their secretaries. The divergent nature of the replies makes it evident that any statement as to the probable effect of the Bill must be largely speculative. The statement runs:—

As the Bill now stands the Insurance Scheme does not apply to certain classes, nor, in the earlier years of its operation, to the families and dependents of the insured. One of the largest of these hospitals estimates that between 60 per cent. and 70 per cent. of the persons now treated in that hospital will be unaffected by the Bill. It further appears from the replies that the balance of opinion amongst these hospitals inclines in the following directions:—

(1) That as regards the number of in-patients it is anticipated that the effect, if any, will be rather to increase the total numbers, even though the proportion of the tuberculous cases may be eventually reduced.

(2) That as regards out-patients it is anticipated that a different class of out-patient may have to be dealt with, and that the effect on numbers, if any, will be towards reduction.

(3) That there is widespread apprehension that the contributions from employers and employed will be reduced.

(4) That Clause 15—"Administration of sanatorium benefit"—will not, it is thought, have any considerable effect in the relief of general hospitals.

(5) That Clause 17, "Power to approved societies to subscribe to hospitals, &c.," is not thought likely to operate beneficially if such contribution is optional, and, if compulsory, there is some apprehension lest this might lead to intervention in management.

(6) That while complete statistics are not available as to the numbers of members of Friendly Societies who at present enjoy the benefits of hospital treatment, it appears that a considerable proportion of adult male patients at these hospitals are members of Friendly Societies or clubs; but that little contribution to these hospitals is at present received from such societies.

The Executive Committee adds to the statement that while under Clause 8, as amended, the Bill purports to confer on insured persons full medical treatment and attendance, including medicines and surgical appliances, the only means for supplying such benefits, in non-tuberculous cases—apart from optional contributions of approved societies to hospitals and charitable institutions (Clause 17)—appears to be by arrangements made with individual medical practitioners—(Clause 14 (1)). The Executive Committee having given due regard to the replies received from the hospitals, shares the opinion generally held that under such arrangements the utilisation of hospitals for more serious cases is not likely to diminish and may, not improbably, increase, with corresponding effect on expenditure, and that the Bill in its present form will tend rather to the reduction than to the augmentation of the hospitals' revenue.

LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY, LIMITED.

The council of this society has forwarded to all its members the following resolutions adopted by it in reference to the Bill. The council urgently requests them to use their influence with their Parliamentary representatives, and with others, to secure for the medical profession the very moderate concessions asked for:—

1. That medical attendance be limited to compulsory contributors, whose total income does not exceed £2 a week.
2. That the appointment and control of the medical officers and the

administration of medical benefits be exclusively in the hands of the Local Health Committee.

3. That two-fifths of the Insurance Commissioners shall be medical men.

4. That the principle be adopted of a wide panel of medical men in each district, including all registered practitioners willing to serve, from whom, subject to the consent of the practitioners selected, the insured person may choose his medical adviser.

5. That this Council are strongly of the opinion that contract work is disadvantageous to the public and unfair to the medical profession; but should a Health Committee under the Bill decide on the adoption of a contract rate for a county the capitation fee should in no case be less than eight shillings, to include only ordinary medical attendance.

6. That Clause 42 of the National Insurance Bill be altered so as to include in the Advisory Committee medical men representing those employed under the Act.

The council of the society has also forwarded copies of the above resolutions to all members of the House of Commons.

Medical News.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the quarterly examination in Practical Pharmacy the following candidates were approved:—

John Gordon Ackland, St. Bartholomew's Hospital; Wilfred Herbert Alderton, London Hospital; Christian Philip Sidney Allingham, London Hospital; John Andrew, St. Bartholomew's Hospital; Gideon Albertyn Beyers, St. Bartholomew's Hospital; Edward Billing, B.A. Cantab., Cambridge and Guy's Hospital; William Somerset Birch, King's College Hospital; Norman Briggs, Leeds University; Lionel Charles William Cane, Guy's Hospital; Hugh Forster Chillingworth, St. Bartholomew's Hospital; Joseph Woods Clayton, London Hospital; Ernest James Cooke, New Zealand University and Guy's Hospital; William Hern Cornelius, L.D.S. Eng., Middlesex Hospital; Cyril Lister Curle, Birmingham University; Harold Archibald Douglas, Cambridge University and St. Bartholomew's Hospital; Herbert Nisbet Eccles, Guy's Hospital; David John Evans, University College, Cardiff; Bernard Creasy Ewens, B.A. Cantab., Cambridge University and St. George's Hospital; Cyril James Gozney Exley, Leeds University and University College; Frederick Ernest Feilden, Middlesex Hospital; Edwin Llewellyn Zenas Fickling, King's College and St. George's Hospitals; Claude Henry Fischel, Middlesex Hospital; Sidney William Fisk, Middlesex Hospital; John Fox-Russell, Middlesex Hospital; Gloster Tyndall Garraway, University College; George Harris Haines, University College; Douglas Noel Hardcastle, St. Mary's Hospital; Robert John Harley-Mason, Middlesex Hospital; Harold James Beresford Heelas, Middlesex Hospital; Arthur Martin Henry, L.D.S. Eng., Guy's Hospital; James Stanley Higgs, St. George's Hospital; Walter Owen Hughes, Liverpool University; Ifan Septimus James, University College; Drue Drury Butler Jay, St. Bartholomew's Hospital; Tudor Philip William John, University College, Cardiff; Frank Edwin Johnson, London Hospital; Gerald Patrick Kidd, St. Thomas's Hospital; Charles Hardiman Laver, Guy's Hospital; Cyril George Learoyd, St. Thomas's Hospital; Sidney John Liddon Lindeman, St. Bartholomew's Hospital; Henry Guy Ludolf, Leeds University; John Edward Carbery Maguire, St. Bartholomew's Hospital; Rodney Honor Maingot, St. Bartholomew's Hospital; Donald Samuel Eccles Milligan, St. Thomas's Hospital; William Hubert Milligan, St. Thomas's Hospital; Charles Frederick Newman, Birmingham University; Ernest Noble Perham, University College and Middlesex Hospitals; Harold Dobson Pickles, Leeds University; Guy Algernon Pratt, Guy's Hospital; Edward Austin Prichard-Evans, University College, Cardiff; Charles Edward Reckitt, Guy's Hospital; Robert Mowat Reid, St. Bartholomew's Hospital; Walter Graham Reynolds, St. Mary's Hospital; Francis Charles Robbs, St. Mary's Hospital; Charles Young Roberts, St. Thomas's Hospital; Laurence Cecil Sebastian Roche, B-ès-Lettres, Caen, St. Thomas's Hospital; Arthur Rose-Innes, University College; Cecil Spurling Staddon, St. Thomas's Hospital; William Fletcher Stiell, St. Thomas's Hospital; Hugh Stott, Sheffield University and University College Hospital; James Llewellyn Montford Symns, B.A. Cantab., Cambridge University and Guy's Hospital; Cedric Rowland Taylor, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Gordon Stuart Terry, Bristol University; Bryan Montague Tuke, Middlesex Hospital; John Wells Whiteman, Middlesex Hospital; Ismail Zaki, University College; and Thomas Fernando Zerolo, St. Bartholomew's Hospital.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Materia Medica and Pharmacy.—H. G. Steel, Durham and St. Mary's Hospital.
Anatomy.—J. C. P. Bayley, Manchester; and W. J. Wood, University College Hospital.
Physiology.—J. C. P. Bayley, Manchester; and G. B. Holroyd, London Hospital.

UNIVERSITY OF OXFORD.—In the examinations for the Diploma in Public Health the following have satisfied the examiners:—

Part I.—William R. Honeyburne, William H. L. McCarthy, and William F. Roach.
Parts I. and II.—Duncan Davidson, B.M., Brasenose, Gilbert H. Dive, Samuel Hamilton, Helen B. Hanson, Lancelot Kilroy, and Murdoch McKinnon.
Part II.—Harold S. Burnell-Jones, David G. Evans, and Francis R. Seymour.

Mr. John H. Evans, M.B., M.Ch. Oxon., F.R.C.S. Eng., has been appointed by the Hebdomadal Council of the University of Oxford representative at the Third International Laryngo-Rhinological Congress, which will be held in Berlin at the end of August.

UNIVERSITY OF LIVERPOOL.—The following awards and appointments have been made in the Faculty of Medicine: Chairman, Professor Benjamin Moore: dean, Mr. K. W. Monsarrat; lecturer in public health bacteriology, Dr. R. Stenhouse Williams; senior demonstrator of anatomy, Dr. W. P. Gowland; assistant demonstrator of anatomy, Dr. T. P. McMurray; J. W. Garrett International Fellow, Dr. O. T. Williams; lecturer in dental mechanics, Mr. Lewis Osborn; Robert Gee Fellow, Dr. J. Campbell; Johnston Colonial Fellow, Dr. A. Adams; Holt Fellow in Physiology, Dr. T. W. Wadsworth; Holt Fellow in Pathology, Dr. R. Stopford Taylor; Torr medal, A. N. Misbah; Gee prize, Miss P. M. Powell, R. Kennon, and A. Seddon (equal); Derby exhibition, H. Nield; Clinical School exhibition, J. R. D. Webb; University scholarship, H. S. Pemberton; Holt medals in physiology, H. S. Pemberton and R. E. Roberts.—The following degrees and diplomas have been conferred:—

M.D.—A. R. Jackson, G. W. N. Joseph, and A. G. W. Owen.
M.B. and Ch.B. (Honours).—J. Homer, R. Kennon, R. H. Knowles, T. H. Martin, H. Nield, A. L. Oluwole, Phoebe M. Powell, and A. Seddon.
M.B. and Ch.B. (Ordinary).—G. S. A. Bishop, W. H. Parry, and J. P. Rafter.
Diploma in Dental Surgery.—W. B. G. Jones.

DEGREES OF M.B. AND CH.B.

Final Examination.—Part I.: R. G. Barlow, A. D. Bigland, F.'G. F. Browne, H. V. Forster, H. W. Jones, N. P. Laing, R. Lee, M. T. Morgan, F. C. Plummer, Frances M. B. Price, H. Seddon, and S. N. Wright. Part II.: G. R. Barlow, A. D. Bigland, F. G. F. Browne, H. V. Forster, R. W. Gemmell, A.V. Glendenning, H. W. Jones, R. Lee, M. T. Morgan, F. C. Plummer, Frances M. B. Price, H. Seddon, T. O. Williams, and S. N. Wright.
Second Examination.—Part A., Anatomy and Physiology: G. D. Harding, R. Martlew. Part B., Materia Medica: Maud E. Bateman, E. B. Marsh, H. S. Pemberton, and J. St. G. Wilson.
First Examination.—Part I., Chemistry and Physics: Ruth I. Bateman, R. L. Blenkhorn, N. B. Capon, E. H. Eastwood, W. T. Evans, H. Garas, G. S. Graham, W. Griffiths, J. P. Johnson, C. H. G. Kelly, A. G. McColl, L. Oldershaw, H. C. Roberts, C. G. Skinner, and H. P. Williams. Part II., Biology: Ruth I. Bateman, R. L. Blenkhorn, N. B. Capon, E. H. Eastwood, W. T. Evans, H. Garas, G. S. Graham, W. Griffiths, W. G. R. Hinchliffe, J. P. Johnson, C. H. G. Kelly, A. G. McColl, E. J. McCormick, H. R. Mansergh, R. J. Minnitt, L. Oldershaw, F. G. Pailthorpe, H. C. Roberts, and C. G. Skinner.

DEGREE OF B.D.S.

First Examination.—G. G. Downie.

DIPLOMA IN DENTAL SURGERY.

Third Examination.—R. N. Lee and W. Williams.
Second Examination.—W. S. Hartley, E. T. Haworth, R. Stoddart, S. S. Tiffin, and S. L. Wallis.
First Examination.—H. W. Flinn, E. T. Haworth, H. O. Sumerling, and B. R. Townend.

UNIVERSITY OF ABERDEEN.—The following degrees were conferred on July 12th:—

Degree of M.D.—William Manson Fergusson, M.B., Ch.B., *Robert Philip Garrow, M.B., Ch.B., *Norman Stephen Gilchrist, M.A., M.B., Ch.B., John Phimister Mitchell, M.B., Ch.B., *Patrick Nicol M.B., Ch.B., *James Rae, M.A., M.B., Ch.B., Alfred John Williamson, M.A., M.B., Ch.B., and William Wood, M.B., Ch.B.
* Commendation for thesis.
Degree of Ch.M.—Frank Pearce Sturm, M.B., Ch.B.
Degrees of M.B. and Ch.B.—Alexander Middleton Brown, M.A., George Paterson Burr, Clifford Cuthbert Chance, William Jenkyns Cruickshank, M.A., Charles Stanley Glass, William Edward Glover, Herbert William Greig, B.Sc., Angus Mackintosh, James Robertson Murray, Peter Reid, and John Ross.
Degrees of M.B. and C.M.—Arthur Cyril Henry Dickman.

Diplomas in Public Health were conferred on:—

David Stewart Garden, M.B., Ch.B. Aberd., Peter Sinclair Hunter, M.A., M.B., Ch.B. Aberd., *David Rorie, M.B., C.M. Edin., George Irvine Thompson Stewart, M.A., B.Sc., M.B., Ch.B. Aberd., James Alex. Tolmie, M.A., M.B., Ch.B. Aberd., and *James Watt, M.A., M.B., Ch.B. Aberd.
* With credit.

The Lyon prize to the most distinguished graduate in medicine of the year and the John Murray Medal and Scholarship to the most distinguished graduate (M.B.) of 1911 were both awarded to James Davidson, M.B., Ch.B.

FOREIGN UNIVERSITY INTELLIGENCE.—*Cracow:* Dr. Franz Krzystalowicz has been appointed Extraordinary Professor of Dermatology. Dr. Erwin Miesowicz has been granted the title of Extraordinary Professor.—

Düsseldorf (*Academy of Practical Medicine*): Dr. Bauer has been appointed Lecturer on Serotherapy, a new departure, it would appear, as serotherapy has not hitherto been considered sufficiently important for a special lecturer to be appointed for it.—*Frankfort:* Dr. A. Reinhardt of Leipsic has been appointed Prosector of the Senckenberg Institute of Pathological Anatomy.—*Giessen:* Dr. Wilhelm Stepp has been recognised as *privat-docent* of Medicine.—*Innsbruck:* Dr. Johann Loos, Extraordinary Professor of Pædiatry; Dr. Geo. Juffinger, Extraordinary Professor of Laryngology; and Dr. Ludwig Mark, Extraordinary Professor of Dermatology, have been promoted to full Professorships.—*Kiel:* Dr. W. Runge has been appointed Oberarzt of the Clinic for Nervous and Mental Diseases, in succession to Dr. Raecke, who goes to Frankfort. Dr. H. Meyer has been recognised as *privat-docent* of Roentgenology and Light Therapy.—*Königsberg:* Dr. Walther Telemann has been recognised as *privat-docent* of Medicine.—*Leipsic:* Dr. Paul Hübschmann has been recognised as *privat-docent* of Pathological Anatomy.—*Munster:* Dr. Otto Krummacher, *privat-docent* of Physiology, has been granted the title of Professor.—*Paris:* Dr. Chauffard, Professor of the History of Medicine and Surgery, has been appointed Professor of Clinical Medicine.—*Prague* (*Bohemian University*): Dr. Ottomar Völker has been appointed Extraordinary Professor of Anatomy. Dr. Johann Jesensky, *privat-docent* of Odontology; Dr. Franz Samberger, *privat-docent* of Dermatology; and Dr. Josef Cisler, *privat-docent* of Laryngology, have been granted the title of Extraordinary Professor.—*Rostock:* Dr. P. Erdmann, *privat-docent* of Ophthalmology, has been granted the title of Professor.—*Vienna:* Dr. Zdarek has been recognised as *privat-docent* of Medical Chemistry.

THE INTERNATIONAL CONGRESS OF UROLOGY.—The triennial meeting of this association will commence its meetings on Tuesday next, July 25th, at the rooms of the Medical Society of London, 11, Chandos-street, W., where all communications should be made to Mr. John G. Pardoe, who is acting as secretary of the congress. There will be a reception of delegates at Princes' Gallery, Piccadilly, W., on Monday evening by Mr. E. Hurry Fenwick, President of the Congress, and Mrs. Hurry Fenwick. A full programme of scientific work has been arranged for the next three days, and on Wednesday evening a banquet will be given by the British members to the foreign members at the Savoy Hotel. The secretary would like to hear at once from members intending to take part in the Congress or attend the functions.

COLONIAL MEDICAL SERVICES.—*West African Medical Staff:* Mr. W. J. B. Carter, medical officer, Gold Coast, has retired, and Mr. W. H. W. Strachan, C.M.G., principal medical officer of Southern Nigeria, and Mr. S. W. Thompstone, C.M.G., principal medical officer of Northern Nigeria, retire on pension. Mr. W. H. Langley, C.M.G., principal medical officer of the Gold Coast, has been promoted principal medical officer of Southern Nigeria, and Mr. W. M. Woods has been selected for appointment as a medical officer in Southern Nigeria. *Other Colonies and Protectorates:* Dr. C. E. Anderson has been selected for appointment as female medical officer in charge of the Lady Havelock Hospital for Women and Children, Colombo, Ceylon, and Dr. R. P. Cockin, district medical officer, Nicosia, Cyprus, has been selected for appointment as resident surgeon of the Colony Hospital and bacteriologist, Grenada, West Indies.

DONATIONS AND BEQUESTS.—Mrs. Lucas, wife of the late Mr. Henry Lucas, who was for many years chairman and treasurer of University College Hospital, has sent to the treasurer of that hospital £1000 on behalf of herself and children for the endowment of a bed in memory of her husband.—Under the will of the late Mr. Rolandi the sum of about £150,000 will be divided equally between the following hospitals:—Italian Hospital, French Hospital and Dispensary, German Hospital, Middlesex Hospital, University College Hospital, Cancer Hospital, Royal South London Ophthalmic Hospital, and Royal Asylum for the Deaf and Dumb at Margate.—Among other charitable legacies bequeathed by the late Mrs. Elizabeth A. Watson is the sum of £10,000 to the trustees of the Nottingham General Hospital to provide accommodation for as many in-patients in that hospital as the interest shall suffice for. The fund is to be kept distinct from the general funds of the hospital and is to be known as "The Watson Bequest."

ON Wednesday the Annual Conference began at Caxton Hall of the National Association for the Prevention of Consumption, when Mr. John Burns, President of the Local Government Board, delivered an address on the work of the Board in this connexion. His Majesty the King sent to the conference from Holyrood Palace a sympathetic message.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The National Insurance Bill.

A HIGHLY interesting debate on the sanatorium treatment of tuberculosis arose in the discussion in committee of the House of Commons of Clause 8 of the National Insurance Bill on Wednesday, July 12th. The debate extended over four hours. Mr. AUSTEN CHAMBERLAIN started it by moving to omit the provision of Clause 8 that amongst the benefits conferred upon insured persons under the Act was "treatment in sanatoria or other institutions when suffering from tuberculosis or such other diseases as the Local Government Board with the approval of the Treasury may appoint." The consideration which the right honourable gentleman submitted to the House was that the Bill was a Bill for insurance against sickness, and that sanatorium treatment was not really the ordinary work of insurance against sickness. There were good grounds for the State treatment of the disease of tuberculosis, but the charges for sanatoriums were much more in keeping with the public charges already assumed by the State and the public authorities than with the insurance charges already included in the Bill. If tuberculosis were to be treated in this special way, why should not the equally terrible scourge of cancer receive similar treatment?

Mr. AUSTEN CHAMBERLAIN'S speech, which was that of a friendly critic of the Bill, gave rise to a succession of instructive utterances. Mr. MUNRO FERGUSON declared that a national campaign against tuberculosis by the Government would not effect anything like the same good as the proposals of the Bill. Mr. LONG demanded that more research should be made into the causes and cure of the disease, and supported his demand from the report of the Royal Commission on Tuberculosis. He asked the Chancellor of the Exchequer not to commit himself to the method of the Bill as a wholly satisfactory method of combating the disease. Sufficient money had not been provided for research work, and vast expenditure on sanatoriums should not be undertaken until more knowledge existed that that kind of treatment was likely to be really effective. A speech by Dr. ADDISON later in the debate was warmly applauded in the House. As a medical man he spoke of the problems connected with the care and cure of tuberculous patients with knowledge and lucidity, and to this kind of speech the House of Commons always lends a willing ear. Dr. ADDISON'S view was that during the last few years, not only in this country but in others, a sufficient amount of very reliable data had been obtained which he thought would more than justify the Chancellor of the Exchequer in pursuing his undertaking with respect to sanatoriums. With regard to cancer, it was safe to say that medical men had no knowledge of the prevention of the disease, but there was a great deal of knowledge as to how to prevent tuberculosis. Dr. ADDISON pointed out the great calls which tuberculosis made on the funds of friendly societies. If the House wanted to protect the insurance fund and sick pay it should undertake the preventional treatment of tuberculosis, which caused a greater charge upon the funds than any other disease. The honourable Member went on to discuss at length the relation of sanatorium treatment to the infected persons, and the necessity of checking the disease in the home. "I am sure," he said in conclusion, "it will be nothing less than a national calamity were this clause to be deleted from the Bill."

Dr. HILLIER, who followed Dr. ADDISON, did not entirely share his conclusions. Dr. HILLIER said that for the State to provide sanatorium treatment merely for those insured under the Bill was neither statesmanlike nor wise. What about other members of the family who contracted phthisis, as they must inevitably do? They would continue to spread the disease. The sanatorium treatment, unless supplemented by other machinery, would be nothing less than a costly palliative and not a remedy. However, he welcomed the attempt on the part of the State to grapple with this great problem, even although he did not think the whole of the proposals were entirely well directed.

Mr. LLOYD GEORGE, when he came to reply to the debate, spoke with confidence of his sanatorium proposals. "From all the inquiries I have made," he said almost in his opening sentence, "I think this experiment will be a success, and I am sure that its success will end in our extending the experiment a good deal further than we propose to do in this Bill." The Chancellor of the Exchequer, however, admitted that the warning not to trust exclusively to sanatoriums in grappling with tuberculosis was very timely and valuable, as sanatoriums could not treat all the cases. The right honourable gentleman then addressed

himself to the question of the success of sanatoriums. He quoted statistics compiled at the Hearts of Oak Sanatorium and the Post Office Sanatorium, and also figures supplied to him by the German Imperial Insurance Office. These, he said, justified Parliament in proceeding with this great experiment. Every inquiry he had made showed that sanatorium treatment did give an increased chance for life to the man who was fighting for his life. Even although sanatorium treatment did not cure consumption, it certainly strengthened people in fighting against the disease. Mr. LLOYD GEORGE indicated that the Government did not intend to exclude other methods of treating tuberculosis. They would, he said, take full advantage of supplementing sanatoriums by other methods or of supplementing other methods by sanatoriums. The Chancellor of the Exchequer further replied to criticisms directed against the Government for refraining to deal with all sufferers from tuberculosis. The Bill only dealt with insured persons. The right honourable gentleman pointed out that a universal extension of the provisions of the Bill would lead to an expenditure of three and a half millions. However, he pointed out that as certain excess charges in the Bill were to be shared by the local authorities and the Treasury, the provision might very usefully be extended to sanatorium benefits as well. If that were carried out he had no doubt the Health Committees and the approved societies would use the sanatoriums for curing the dependents of insured persons. It would then be open to the local authority to approach the Treasury with a view to increasing the accommodation. The Treasury would undertake half the expense and the local authority the other half. In conclusion, he warned the House not to overburden the scheme by attempting too much.

Several interesting speeches were made after Mr. LLOYD GEORGE resumed his seat. Dr. CHAPPLE spoke of the practical difficulties which had to be overcome in the treatment of tuberculous patients. He admitted the limitations of sanatoriums, but claimed that better results in the care of tuberculosis had followed the erection of sanatoriums than any other treatment known to medical science. Dr. ESMONDE also showed the medical man's intimate knowledge of the ravages of the disease amongst the industrial population. Members listened with deep attention to his description of the difficulty of inducing the workman stricken with tuberculosis to leave his home. He earnestly asked the Chancellor of the Exchequer to take into consideration the treatment of persons in their homes. He deprecated spending great sums of money at the present stage in the erection of large buildings.

Mr. AUSTEN CHAMBERLAIN ultimately withdrew his amendment, remarking that the debate had been amply justified. He observed that he and his friends were quite satisfied with Mr. LLOYD GEORGE'S statement that although the experiment of sanatoriums was a large one it was still to be regarded as only an experiment, and not only as an experiment but as one amongst several for combating and fighting tuberculosis.

The debate was generally regarded by the House as most useful and instructive, but its length permits only its salient points to be touched upon.

On Monday, July 17th, the House of Commons made further progress with the consideration of Clause 8, which sets out the benefits to which insured persons are entitled. The principal topic touched in the course of the discussion was the maternity benefit, which is 30*s*. The point that a married woman, who was herself an insured person, would find herself insured twice over, was brought to the notice of the Government. The Chancellor of the Exchequer, who admitted that there was an unfairness in this arrangement, promised an amendment to transfer the maternity benefit to the husband's fund and to give the wife her 30*s*. in the form of sick pay. This provision was subsequently embodied in the Bill.

Before the House agreed to Clause 8 in its amended form on Tuesday afternoon Mr. AMERY put in a plea that the health campaign should be extended to the scourge of syphilis as well as to that of tuberculosis. The honourable Member in general terms indicated the effect of the former disease on the health of the nation and the danger to the community of its presence. The essential thing in dealing with syphilis was that the treatment should be cheap and accessible, and such that the victims of the disease should have confidence in. Mr. AMERY did not ask that the Chancellor of the Exchequer should set aside a large sum of money for dealing with the problem, but he suggested that the right honourable gentleman should contemplate a serious national campaign to deal with it. The line suggested was that institutions for treatment should be opened in certain districts in order to gain experience and to discover how sufferers from the disease could most effectively be treated. Mr. MCKENNA, the First Lord of the Admiralty, who is assisting Mr. LLOYD GEORGE in the conduct of the Bill, acknowledged the serious tone of Mr. AMERY'S remarks. He pointed out that the phraseology of the clause gave the Local Government Board power to deal with "other diseases" besides tuberculosis, and he had no doubt that the views of Mr. AMERY would receive the serious consideration of that department. Clause 8, which contains a good many amendments as the result of the deliberation in committee, was ultimately agreed to.

On Wednesday the House of Commons continued to deal with points concerning benefits and the machinery by which they are to be administered, but the case of the medical profession was not reached. It will be considered on Clause 14, which may be reached next week. One of the features of the debates on the Bill has been the frequency of the demands to extend its limits and the successful resistance to some of them by the Chancellor of the Exchequer on the ground that they would conduce to instability of finance.

National Insurance Bill Amendments.

Several fresh amendments have been set down to Clause 14 of the National Insurance Bill with reference to the administration of medical benefits.

Dr. ADDISON gives notice of one to the following effect: "Subject to regulations by the Insurance Commissioners, it shall be lawful for any insured person, in lieu of receiving medical attendance and treatment under such arrangements as aforesaid, to enter into agreement with any duly qualified medical practitioner for medical attendance and treatment, and any approved society or Local Health Committee which would otherwise have been charged with the duty of administering his medical benefit shall contribute towards the cost of the medical attendance and treatment of such person under such agreement sums not exceeding in the aggregate the cost which the society or committee would otherwise have incurred in providing medical attendance and treatment for him."

Colonel HICKMAN proposes to insert in the clause the following provision: "Where any medical man can prove to the satisfaction of the Insurance Commissioners that within ten years before the passing of this Act he has paid a sum of money for the goodwill of his practice, and that, not being a selected medical man under the provisions of this Act, he thereby loses not only the sum paid for the goodwil of his practice, but a great part of the practice itself, the Commissioners shall make such compensation as they may think fit."

Sir PHILIP MAGNUS has given notice of his intention of moving an amendment in these terms: "Provided that no insured person shall be entitled to medical benefit if his average income from all sources exceeds £2 a week, but in any such case he shall, in lieu of the medical benefit to which he would be otherwise entitled under this part of the Act, be entitled to receive a cash payment towards the expenses of medical treatment, the amount of such payment to be calculated in accordance with tables to be prepared by the Insurance Commissioners."

Somewhat different phraseology to accomplish a similar object is adopted by Mr. AMERY, who proposes that "no insured person shall be entitled to medical benefit if his average income from all sources in the calendar year preceding the date at which he became entitled to sickness benefit exceeded the sum of £100, but in any such case he shall, in lieu of the medical benefit to which he would otherwise be entitled under this part of this Act, be entitled to receive a cash payment towards the expenses of medical treatment, the amounts of such payment to be in accordance with tables to be prepared by the Insurance Commissioners."

On Clause 15 (administration of sanatorium benefit) Mr. DAVID DAVIES will bring forward an amendment that "no person shall be entitled to treatment in a sanatorium unless the Local Health Committee considers the case one suitable for sanatorium treatment, and admission to such treatment shall be conditional on the case having been previously notified to the public health authority or to such authority as the Insurance Commissioners may appoint."

Mr. EVELYN CECIL has given notice of the following amendment to Clause 14: "And any Health Committee may make arrangements with hospitals for the reception of insured persons in the case of accidents or operations or such other serious causes as the practitioners may be unable or unwilling to treat in the patient's house, or it may make grants out of the medical benefit funds to any hospitals which have rendered such services."

Dr. HILLIER on the same clause will move that the medicines provided under the clause "shall be dispensed by a pharmaceutical chemist, or chemist and druggist, under the Pharmacy Acts, 1852 and 1868, or by a certified assistant to an apothecary under the Apothecaries Act, 1815, or by persons who for seven years prior to the passing of this Act have been employed as dispensers to medical men."

Geneva Convention Bill.

The Geneva Convention Bill, which has been read a second time in the House of Commons, is designed to give the effect of a statutory enactment to certain matters arising out of the Geneva Convention of 1906. That Convention decided that measures should be taken to prevent the fraudulent use of the Red Cross flag and to limit the employment of the badge to the Red Cross Society, which assisted the sick and wounded in time of war.

HOUSE OF COMMONS.

WEDNESDAY, JULY 12TH.

Maternity Orders in London.

Mr. CROOKS asked the President of the Local Government Board whether he could obtain for the information of the House the number of maternity orders giving the right to free attendance by a medical man from the various hospitals maintained by voluntary contributions in London.—Mr. BURNS replied I understand that in 1909 5134 confinements occurred in London in lying-in hospitals, and 24 875 in connexion with free hospital maternity charities at home, being a total

of 30,007. Assuming one birth to a confinement, this implies that about 25·4 per cent. of the total births in London were gratuitously attended in connexion with these charities.

Mr. CROOKS asked what was the number of maternity orders issued by the boards of guardians (1) in London, (2) in the provinces, and (3) in Wales, differentiating between institution and home attendance of the medical officer.—Mr. BURNS answered: According to the latest returns 3125 cases were admitted to maternity wards of London workhouses and infirmaries during the year 1910. The number of midwifery orders given to district medical officers was 1265 and to midwifery nurses appointed by guardians 329. I am not able to give corresponding figures for the rest of the country.

Medical Inspection of School Children.

Mr. WEDGWOOD asked the President of the Board of Education whether it was the practice of medical inspectors of school children to make recommendations on the medical card of each child as to treatment or care; and whether the inspectors of different authorities differed in practice on this point.—Mr. RUNCIMAN said in reply: In most cases the defect is referred to the parent in a special note. There are so many varieties of practice that it is impossible to deal with them in an oral answer. My honourable friend will find much information on this point in the latest report of the chief medical officer of the Board.

Mr. WEDGWOOD: Can the right honourable gentleman say whether the schools under the London County Council are worse than those in the rest of the country?—Mr. RUNCIMAN: Quite recently I have had to criticise the methods adopted by the London County Council, and I see there are considerable improvements in progress by that Council and the medical officers.

Mr. WEDGWOOD asked whether the right honourable gentleman could say how many schools on the average were allotted to one London County Council medical inspector for inspection; how many visits and how many hours a year on the average a medical inspector in the London area gave to each school; and how many children of each school he inspected individually at each visit.—Mr. RUNCIMAN replied: So far as I can ascertain from the information at present at my disposal, I think the answer to the first part of the question is 9·2, but I cannot pretend to an accurate knowledge from month to month of the precise ways in which the various medical inspectors of local education authorities are employed. The actual number of visits per school and the number of hours spent in each school naturally vary with the number of children in average attendance. No general conclusions could properly be drawn from the averages suggested in the question, which are misleading unless account is taken of the varying sizes of the schools. The number of children inspected at each visit appears to be, in the case of the older children, about 20 to 25, and more in the case of infants. A visit extends over two and a half hours.

National Insurance Topics.

Mr. HASTINGS DUNCAN asked the Chancellor of the Exchequer whether Health Committees appointed under Clause 14 of the National Insurance Bill to administer medical benefit might include medical men practising homœopathy in their list of qualified medical practitioners.—Mr. LLOYD GEORGE replied: The answer is in the affirmative.

Major HENDERSON asked whether, under the insurance scheme, in the event of an insured person becoming demented and detained in a public institution, the whole of his invalidity money would be paid to his dependents without deduction.—Mr. LLOYD GEORGE answered: In the circumstances described the disablement benefit would be paid to, or applied in whole or in part for the relief or maintenance of, the dependents of the insured person as the society or committee by which the benefit is administered think fit. No part would be payable to the institution, but the dependents would have no absolute right to the whole.

THURSDAY, JULY 13TH.

National Insurance Topics.

Mr. GIBBS asked the Chancellor of the Exchequer whether he would be willing favourably to consider an amendment to the National Insurance Bill providing for the compensation of such medical men as should be able to prove financial loss owing to the operation of the Act.—Mr. HOBHOUSE (on behalf of Mr. Lloyd George) replied: My right honourable friend anticipates that the operation of the National Health Insurance will cause financial gain rather than loss to medical men.

Mr. POINTER asked whether the right honourable gentleman had considered the case of the medical aid societies at work in various parts of the country, which engage, pay, and control a medical practitioner of their own, who prescribed for and attended the members of the society, using the medicines and drugs purchased by the society; and whether they would be affected by the National Insurance Bill, and if so how, and if adversely what provision he intended to make to enable them to continue their work.—Mr. HOBHOUSE said in reply: A medical aid society which is prepared so to extend its operations as to administer all the benefits provided under the National Health Insurance can become an approved society. Under the proposals of the Bill a society which desires to confine its activities within the existing limits can readily make such arrangements with the approved societies through which its members are insured to enable it to continue to administer their medical benefit and to receive the funds available for that purpose out of their contributions.

Medical Inspection of School Children.

The House went into Committee of Supply on the Education vote.

Mr. RUNCIMAN (President of the Board of Education), in the course of his statement, said that at the time when Parliament was discussing a National Insurance Bill it was well to take into account that under the organisation of the local education authorities 6,000,000 children were already subject to medical inspection. In the whole of the authoritative areas there were 322 medical officers who were carrying out this work. Last year no less than 2,000,000 children were examined by the school doctors. Of these no less than 10 per cent. were found to have defective vision. Some 3 to 5 per cent. had defective hearing; 8 per cent. had adenoids or enlarged tonsils; 1 per cent. had ringworm and 1 per cent.—in some cases rising to over 4 per cent.—were suffering from tuberculosis in a readily recognisable form. 1 per cent. were suffering from heart disease. From 20 to 40 per cent. had extensive decay of the teeth. These were facts which, when brought home to the local authorities, made them at once agree, even at the expense of their most economical ratepayers, to embark upon medical treatment. Inspection was of some good, but it did not go the whole way. If inspection was to yield practical results it must lead up to treatment in one form or another, either privately or organised by the local education authority. But if it was to be undertaken by the local education authority that could not be done under the statute until four points were fulfilled:—(1) Before treatment was undertaken the inspection must be satisfactorily organised; (2) the treatment based on prevention schemes of treatment should be coördinated with the work of preventive medicine already conducted in the area and not organised apart from it; (3) the authority which was responsible for the inspection should also be responsible for the treatment; (4) before the authority undertakes this work all other means should be exhausted—that was to say, that the parent could not himself have the child treated by a private practitioner. But there was work which the private practitioner could not do and which was much better done by organisation. Even such a common thing as ringworm yielded best to X ray treatment, and very few private practitioners had the necessary apparatus. Therefore he thought it was as well to have the school medical service organised in harmony with the public health service already in existence. The Board of Education preferred the school medical officer to be the medical officer of health—and he was in a very large number of cases—something like 250 out of 320. Another thing of great value was that if the school medical officer was not the same as the medical officer of health, he should at least be in close touch with the borough medical officer, for it was extremely desirable that the information collected by the school medical officer and by medical inspection should be passed on to the medical officer of health as quickly as possible. The reason of it was that the sanitary control of the schools was in the hands of the sanitary officer. Notification, disinfection, and sanitation of the home were in the hands of the sanitary authority. The right of entry into the house of the ailing child was an advantage possessed by the medical officer of health. All that meant that the medical officer of health was an essential officer in the economy of the school medical service. That was why the Board asked the local authorities to work in complete harmony with the existing public health authority. He took as an example tuberculosis. The first thing necessary to find out was the cause of tuberculosis and the source of the trouble. The medical officer of health had a record of the child's birth and he knew something about the home environment and the tracing of the source of infection. The school medical officer detected the disease at the time, and then the child was dealt with by the local education authority, which body was responsible for the improvement of hygiene in the schools, for open-air schools, and other means for dealing with each case. Finally, it was the sanitary authority which disinfected the home and closed up the case. The same held good in regard to verminous cases, and it was equally true with regard to infectious diseases. The medical officer of health undertook the various medical duties. He linked up the home with many of the public services, and that was the reason why the Board of Education was taking the view that a conjunct arrangement must be worked on if medical inspection and treatment were to be at all effective. The charge made with regard to medical inspection was that it would be likely to lead to a decrease in the sense of responsibility of the parents. Quite the contrary had been the experience. The truth was that a great number of parents were reluctant to believe that anything was wrong with their children. It often came as a complete surprise to them to learn that there was. There was a minority of people who resented medical treatment, but on the whole the vast majority were surprised when they heard of illness among their children, and they believed it to be their duty to make the care far better than before. A great many of the medical complaints were really the effect of defective mothering. By giving a little assistance, guidance, and hints to the mother and making her improve the home surroundings the health of the children was improved and the best use was made of medical inspection. The best way of dealing with a great many of these cases was to make the nursing better and to improve cleanliness, and that was the practical result of the institution of medical inspection. So far from decreasing the sense of responsibility, it opened the eyes of many parents to the necessity of better treatment for their children. He would not trouble the committee by telling it the large number of local authorities who had made special arrangements for carrying out this Act. He would like to point out the number of school clinics which had been instituted in various parts of the country, and he desired to say that where board school clinics were started full advantage ought to be taken of the service already available. Special treatment, he would like to add, was now provided in many areas for feeble-minded and defective children and for children who were deaf or blind.

MONDAY, JULY 17TH.

Tuberculosis in the Navy.

Mr. MCKENNA informed Mr. WORTHINGTON-EVANS that there was no provision for the treatment in sanatoriums of men on the active list of the Royal Navy who were suffering from tuberculosis, and so far as was known no men on active service were treated in such sanatoriums in 1909.

Tuberculosis in the Army.

Mr. WORTHINGTON-EVANS asked the Under Secretary of State for War whether he could state the number of men on active service who in the year 1909 were provided with treatment for tuberculosis in sanatoriums; whether there was now any provision made for treatment of men on active service in sanatoriums; and what, if any, deductions from pay were made when such treatment was given.—Colonel SEELY replied: No soldier while still serving with the colours is sent to a sanatorium, and therefore no question of a deduction for hospital stoppages arises on this account. As soon as a soldier is diagnosed to be suffering from tuberculosis steps are taken to invalid him from the service and his retention in a military hospital is only temporary until he is fit to travel. Notification is duly made to the medical officer of health of the place to which the man is to be sent on discharge; but I am informed that in nearly every case the regimental authorities take steps to secure the man's reception in a sanatorium, the cost being in many cases provided by the officers of the regiment.

National Insurance Topics.

Mr. COOPER asked the Chancellor of the Exchequer whether, in the case of an insured person requiring and being ordered nourishing diet, such as milk, beef-tea, wine, &c., or simple appliances such as bandages

and trusses, arrangements would be made for their supply; and whether they would be a proper charge on the National Insurance Fund.—Mr. HOBHOUSE (on behalf of Mr. LLOYD GEORGE) replied: Simple appliances can be supplied as part of medical benefit, but articles of diet cannot. In this respect the National Health Insurance Scheme will conform to the ordinary practice of Friendly Societies.

Mr. SANDYS asked how many representatives of the medical profession were to be included amongst the Insurance Commissioners, on the Advisory Committee, and on the Local Health Committees respectively; and whether it was intended under the National Insurance Bill to sanction the appointment of local medical committees with powers to act in conjunction with Local Health Committees for the purpose of making suitable arrangements in connexion with the administration of medical benefits.—Mr. HOBHOUSE answered: The Insurance Commissioners will be an executive, not a representative, body, but my right honourable friend intends that at least one of their number shall be a medical man. The medical profession will certainly be represented on the Advisory Committee, and the precise number of representatives cannot be settled until the members of the committee and the other classes of persons to be represented have been decided on. The Local Health Committee must, under the proposals of the Bill, include at least two qualified medical practitioners.

Mr. H. LAWSON asked whether rules would be made and issued, either by the Treasury or the Local Government Board, in regard to the division of medical practice as between doctors contracting under the National Insurance Bill in the same area in regard to the number of patients, especially those with chronic illness and in regard to the distance from the doctor's house for visiting purposes, in regard to night calls, having in view the present custom and scale of fees.—Mr. HOBHOUSE said in reply: The answer is in the negative.

Mr. POINTER asked whether duly qualified herbal practitioners would be allowed to practise under the terms of the National Insurance Bill in cases where the insured person preferred their services to those of the ordinary medical practitioner.—Mr. HOBHOUSE answered: No practitioner who has one or other of the qualifications enumerated in connexion with the Medical Acts would be ruled out by the terms of the Bill.

Incompatibility and Some of its Lessons. By Walter G. Smith, M.D., King's Professor of Materia Medica and Pharmacy, School of Physic, T.C.D.; Physician to Sir P. Dun's Hospital; Ex-President, R.C.P.I. Second edition. Price 1*s.* net.

URBAN UND SCHWARZENBERG, Berlin und Wien.

Lehrbuch klinischer Untersuchungsmethoden. Für Studierende und Aerzte. Von Dr. med. Theodor Brugsch, Universitäts professor, Assistent der II. Mediz. Universitäts-Klinik in Berlin, und Dr. med. Alfr. Schittenhelm, a.o. Professor der Klinischen Propädeutik und Geschichte der Medizin in Erlangen. Zweite erweiterte Auflage. Price, paper, M.15; bound, M.17.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BURNET, JAMES, M.D. Edin., M.R.C.P. Edin., has been appointed Examiner in Materia Medica to the University of Aberdeen.

CRABB, R. L., M.B., B.S. Lond., has been appointed Obstetric Assistant to University College Hospital.

CURRY, A., L.R.C.P. & S. Irel., has been appointed Anæsthetist at the Hospital for Women and Children, Leeds.

DAWNAY, A. H. PAYAN, F.R.C.S. Eng., has been appointed Ophthalmic Surgeon to Out-patients at the Great Northern Central Hospital.

FOX, S. C. GUNDRY, M.R.C.S., L.R.C.P. Lond., has been appointed Senior Medical Officer at Perak, Federated Malay States Medical Service.

GILFILLAN, S. J., M.B., C.M. Edin., has been appointed Medical Superintendent of Colney Hatch Asylum.

HART, W. S., M.B., Ch.B., has been appointed Anæsthetist at the Hospital for Women and Children, Leeds.

KISCH, HAROLD A., M.B., B.S. Lond., F.R.C.S. Eng., has been appointed Assistant Surgeon to the Royal Ear Hospital.

MOORE, F. CRAVEN, M.D. Vict., F.R.C.P. Lond., has been appointed Honorary Assistant Physician to the Manchester Royal Infirmary.

ODELL, WILLIAM, M.D. Durh., F.R.C.S. Eng., has been appointed Honorary Consulting Physician to the Western Hospital for Consumption, Torquay.

PAUL, J. E., M.D. Lond., M.R.C.S., L.R.C.P. Lond., has been appointed Honorary Physician to the Western Hospital, Torquay.

RAE, C. G., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer of the Southern Division of the Wick Parish Council.

RAYNER, H. H., M.B., B.Ch. Vict., F.R.C.S. Eng., has been appointed Honorary Assistant Surgeon to the Manchester Royal Infirmary.

SANCTUARY, T., M.D. Edin., has been appointed Medical Officer of Health for the Duffield Rural Sanitary District.

SHAND, G. ERNEST, M.B., B.S. Aberd., has been appointed Senior Medical Officer at the City Asylum, Birmingham.

SIKES, A. W., M.D. Lond., F.R.C.S. Eng., M.R.C.P. Lond., has been appointed a Half-time Assistant Medical Officer in the Education Department of the London County Council.

TASKER, H. L., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon at University College Hospital.

WALSHE, F. M. R., M.B., B.S. Lond., has been appointed House Surgeon at University College Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ABERDEEN, KINGSEAT ASYLUM.—Assistant Medical Officer. Salary £120, with board, &c.

BANGOR, CARNARVONSHIRE AND ANGLESEY INFIRMARY.—House Surgeon. Salary £100 per annum, with board, washing, and lodging.

BIRKENHEAD AND WIRRAL CHILDREN'S HOSPITAL, Woodchurch-road, Birkenhead.—House Surgeon. Salary £100 per annum, with board, residence, and laundry.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—Junior House Surgeon. Salary £70 per annum, with board and residence. Also Locum Tenens to act as Junior House Surgeon. Salary 3 guineas weekly, with board and lodging.

BIRMINGHAM CITY ASYLUM.—Junior Assistant Medical Officer. Salary £150 per annum, with board, apartments, and laundry.

BODMIN, CORNWALL COUNTY ASYLUM.—Third Assistant Medical Officer, unmarried. Salary £140 per annum, with rooms, rations, laundry, and attendance.

BRIDGWATER HOSPITAL.—House Surgeon, unmarried, for six months. Salary at rate of £100 per annum, with board, lodging, and washing.

BRIGHTON, ROYAL SUSSEX COUNTY HOSPITAL.—House Physician, unmarried. Salary £80 per annum, with apartments, board, and laundry.

BURNLEY, VICTORIA HOSPITAL.—Junior House Surgeon for six months. Salary at rate of £80 per annum, with residence, board, and washing.

BUXTON, DERBYSHIRE, DEVONSHIRE HOSPITAL.—Assistant House Surgeon for six months. Salary £70 per annum, with apartments, board, and laundry.

CAMBERWELL, GORDON-ROAD WORKHOUSE, Peckham.—Assistant Medical Officer. Salary £120 per annum, with apartments, board, and washing.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's Inn-road, W.C.—Assistant Surgeon.

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Clinical Assistant for three months.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL.—House Physician. Salary £70 per annum, with board, apartments, and laundry.

COLCHESTER, ESSEX COUNTY HOSPITAL.—House Physician. Salary £80 per annum, with board, residence, and washing.

COVENTRY AND WARWICKSHIRE HOSPITAL.—Junior House Surgeon. Salary £80 per annum, with rooms, board, washing, and attendance.

DEVONPORT, ROYAL ALBERT HOSPITAL.—Assistant House Surgeon for six months, unmarried. Salary at rate of £50 per annum, with board, apartments, and laundry.

DUDLEY, GUEST HOSPITAL.—Assistant House Surgeon for six months. Salary £75 per annum, with residence, board, and washing.

DUMFRIES, CRICHTON ROYAL INSTITUTION.—Pathologist and Clinical Pathologist. Salary £250 per annum, with quarters, board, and laundry.

ENNISKILLEN, FERMANAGH COUNTY HOSPITAL.—House Surgeon. Salary £72 per annum.

FRENCH HOSPITAL, 172, Shaftesbury-avenue, W.C.—Second Resident Medical Officer, unmarried. Salary £50 per annum, with board and laundry.

FULHAM ANTITUBERCULOSIS DISPENSARY.—Medical Officer. Salary £250.

GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—Assistant House Surgeon. Salary £75 per annum, with board, residence, and laundry.

HEMEL HEMPSTEAD, HERTS, WEST HERTS HOSPITAL.—Resident Medical Officer. Salary £100 per annum, with rooms, board, and washing.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—House Physician for six months. Salary 30 guineas.

KINGUSSIE, SCOTLAND, GRAMPIAN SANATORIUM FOR TUBERCULOSIS.—Resident Physician. Salary £100 per annum.

LONDON, SANITARY INSPECTORS' EXAMINATION BOARD.—Four Examiners.

MACCLESFIELD, CHESHIRE COUNTY ASYLUM, Parkside.—Junior Assistant Medical Officer, unmarried. Salary £150 per annum, with board, apartments, and laundry.

MILLER GENERAL HOSPITAL FOR SOUTH-EAST LONDON, Greenwich-road, S.E.—Honorary Physician. Also Pathologist and Registrar. Salary £75 per annum.

METROPOLITAN HOSPITAL, Kingsland-road, N.E.—Assistant House Surgeon for six months. Salary at rate of £40 per annum, with board and washing.

NEWCASTLE-UPON-TYNE, UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.—Demonstrator of Anatomy.

NORWICH, NORFOLK AND NORWICH HOSPITAL.—House Surgeon, unmarried. Salary £80 per annum, with board, lodging, and washing.

NOTTINGHAM GENERAL DISPENSARY.—Assistant Resident Surgeon, unmarried. Salary £160 per annum, with apartments, attendance, &c.

NOTTINGHAM WORKHOUSE INFIRMARY.—Resident Assistant Medical Officer, unmarried. Salary £130 per annum, with apartments, board, washing, and attendance.

PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham, N.—Junior House Physician. Salary £50 per annum, with residence, board, and laundry.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, N.E.—House Surgeon and Two House Physicians, all for six months. Salary in each case at rate of £80 per annum, with board, residence, and washing.

ROTHERHAM HOSPITAL AND DISPENSARY.—Assistant House Surgeon. Salary £80 per annum, with board, lodging, and washing.

ROYAL EAR HOSPITAL, Dean-street, Soho, W.—Assistant Surgeon.

ST. PANCRAS INFIRMARY (SOUTH) AND WORKHOUSE.—Assistant Medical Superintendent and Assistant Medical Officer. Salary at rate of £135 per annum.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of a vacancy for a Certifying Surgeon under the Factory and Workshop Act at Glastonbury, in the county of Somerset.

Births, Marriages, and Deaths.

BIRTHS.

CADDY.—On June 25th, the wife of Adrian Caddy, M.D., F.R.C.S., of Harington-street, Calcutta, of a daughter.

SEARLE.—On July 8th, at Bridge-street, Cambridge, the wife of C. F. Searle, M.B., of a son.

SPITTA.—On July 13th, at Bolton-street, Mayfair, the wife of Harold Spitta, M.D., of a daughter.

MARRIAGES.

CORNISH—LLOYD.—On July 13th, at St. Ann's Church, Kew Green, Charles Vivian Cornish, F.R.C.S. Edin., to Ethel Saunderson, younger daughter of the Rev. Frederick Charles Lloyd.

JORDAN—BRUMLEU.—On July 12th, at Holy Trinity Church, Sidcup, by the Rev. J. Foster Lepine, Alfred Charles Jordan, M.D., of 14, Weymouth-street, W., third son of the late Albert Jordan, of Bowden, Cheshire, to Christina, third daughter of the late Charles Brumleu, of Mossbank, Sidcup.

MUSSEN—OAKSHOTT.—On July 12th, at St. Peter's, Rock Ferry, Arthur Augustus Mussen, M.D., to Norah Elsie, youngest daughter of the late Thomas William Oakshott, J.P., and Mrs. Oakshott, Derby House, Rock Ferry.

OAKLEY—BROMLEY.—On July 12th, 1911, at Great Nest Church, Salop, by the Vicar, the Rev. F. J. Stanley, George Gardner Oakley, M.R.C.S. Eng., L.R.C.P. Lond., eldest son of Dr. J. Oakley, J.P., Holly House Halifax, to Mary Gardner Bromley, second daughter of Richard Bromley, Esq., Felton Butler, near Shrewsbury. "At Home," Holly House, Halifax, Sept. 5th, 6th, and 7th.

RIDOUT—HOOPER.—On July 11th, at St. Jude's, Southsea, Charles Archibald Scott Ridout, M.S., M.B. Lond., F.R.C.S. Eng., to Gladys Mary, eldest daughter of the late Henry Lawrence Hooper and Mrs. Tyson, of Spencer-road, Southsea.

WATKINS—CROW.—On July 11th, at Croydon, Frank A. Watkins, M.R.C.S., L.R.C.P., L.S.A., of Merton Lodge, Denmark Hill, to Clara Elizabeth Crow, younger daughter of W. M. Crow, of Croydon.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

"BENIGHTED ITALY."

IT used to be a proud distinction of the profession that its members might be summoned by duty to the lowest haunts of vice and crime and their persons be secure from aggression or violence, where no other intruder, not even the clergyman, could enter an appearance without danger, except when accompanied by an imposing police force. Now, it seems, in the "Third Italy," which has lately been celebrating its "new departure" on the line of progress, this distinction no longer holds good. A well-informed correspondent writes: "From the Alps to Etna, from the Venetian territory to Palermo, the populace in town or country has risen in revolt against the divisional practitioners or sanitary officers when in the very act of protecting them from epidemic disease, causing them to run for their lives and thereafter to find that their houses had been set fire to and their families threatened with extinction in the flames. Barely six miles from Palermo, the seat of a university, a cathedral city, and a great *entrepôt* of traffic and tourist resort, the population of Belmonte Mezzagno assembled *en masse* on the night of July 10th before the town-hall, where the syndic, the town council, the departmental practitioner, Dr. Genova, and other functionaries of the commune had met to take opportune measures for the public health, threatened, *inter alia*, by cholera. A storm of hooting and hostile cries brought the prefectoral commissioner to the balcony, where he vainly tried to appease the infuriated mob. His words were drowned in a volley of invectives, closely followed by a shower of stones, which made havoc of the windows of the town-hall. The syndic and others of the councillors effected their retreat through a back door, while the town clerk was seeing to the closure of every point of access. By this time the assailants had taken to their revolvers, while others of them were using logs of wood as battering-rams against the main entrance. The besieged party (for such they now were) put out the lights, but the fusillade of stones and pistol-shots continued and forced them speedily to seek such shelter as they could in the corners of the several rooms. Meanwhile the brigadier of carabineers with a few linesmen succeeded in occupying the immediate front of the building, but the mob, which had added to its numbers, maintained its steady fire of projectiles, making the position of the besieged every moment more critical. Fortunately the town clerk bethought him of a door to the back which had been closed up with plaster, and he and the others by dint of their penknives got down to the door-handle, which by good luck they turned and so effected their escape to the open country. The mob on ascertaining this became still more infuriated and renewed their efforts to force the main entrance, shouting 'Morte al medico! Morte al commissario!' ('Death to the doctor! Death to the commissioner!'). Having got inside the building they burst through the door improvised by the besieged and gave chase, but without overtaking the fugitives. They then marched to Dr. Genova's private residence, broke into it, sacked it, and flung the fragments of furniture into the street. They finally set fire to it and put the neighbouring houses in imminent danger of being involved in the conflagration. The brigadier with his handful of soldiers could no longer protect the town-hall which the mob now proceeded to set on fire, with the result that the municipal registers were all destroyed. Only the arrival of a strong contingent of carabineers succeeded in quelling the riot and arresting the ring-leaders and some of their abettors." A similar uprising, equally inspired by superstitious dread of hygienic precautions and the institution of a lazzaretto, is reported from Venice, doubtless to be followed by others. Surely "the schoolmaster abroad" has been very far afield, and the priestly confraternities culpably negligent of their duty as mediators, when such scenes are witnessed in a country whose Past has figured so honourably in the advancement of medicine.

A MYSTERIOUS BURNING FATALITY.

AN inquest was held recently at Marlborough upon the body of a little girl, 6 years of age, who was burned to death owing to her clothes catching fire in the street, there being no evidence obtainable to account for their ignition. The child was standing in the High street, when suddenly she was seen to be enveloped in flames, and a lady, who suffered some injury by her prompt and plucky effort to save her, succeeded in extinguishing the flames, but not before the child had been severely burnt. It was thought that a motor-car which had just passed near her had set her on fire, and to enable the possibility of such a thing to be tested the coroner rather ingeniously caused a reconstruction of the scene to take place before the jury and himself on the actual spot, and with the witnesses of the occurrence present in the places that they had occupied. The car suspected was backed out of the garage by its driver just as it had been on the day of the burning with a piece of flannelette saturated in petrol placed near the exhaust pipe, from which it had been suggested that a spark might have escaped. The test took place and nothing occurred. The flannelette did not catch fire, and expert evidence was given in confirmation of this negative result, when the inquest was resumed in more normal fashion, to the effect that no spark could be emitted from the exhaust when the engine was running and that it had never occurred to anyone before the case in question that anything could catch fire from the exhaust. The jury returned an open verdict and the manner in which the poor little girl lost her life remains for the present unexplained. It is of course possible to conjecture that she was playing with matches before the car passed her or that some careless smoker had thrown a lighted match upon or near her clothes, which consisted apparently to some extent of flannelette. That they should become fiercely alight before they were noticed is a curious circumstance, and it was hardly to be expected that responsibility would be brought home to the motor-car. With every variety of inflammable material, constantly brought close in the streets of towns to every part of motor-cars of all classes, such an occurrence could hardly remain unique if it were possible for it to happen in anything like the manner suggested.

THE NECESSITOUS LADIES' HOLIDAY FUND.

To the Editor of THE LANCET.

SIR,—You were good enough on previous occasions to allow me space in your valuable paper to appeal for contributions to provide holidays by the sea- or country-side for necessitous ladies. Through the generosity of your readers I was enabled to bring rest and refreshment to many. I appeal again for help to send away governesses, typewriters, hospital nurses, secretaries, musicians, actresses, and ladies engaged in other professions who, unable to provide holidays for themselves and without the possibility of earning money in the summer months, are left behind in London exposed to the sufferings attendant on poverty.

In this happy Coronation year I plead for those too proud to plead for themselves, for the overworked and unfortunate, and more especially for those broken down in health.

All contributions sent to me to appended address will be gratefully distributed. I am, Sir, yours faithfully,

48, Upper Berkeley-street, London, W. CONSTANCE BEERBOHM.

DEATH FROM ANTHRAX IN A LABORATORY.

AT an inquest held recently at St. Pancras on the body of Henry Stephen Thurston, laboratory attendant at University College Hospital, it was proved that the deceased had died from anthrax poisoning. He had developed a boil on the side of his neck which had been removed after microscopical examination of matter obtained from it had shown that it was due to anthrax. After the operation he had progressed so favourably as to appear out of danger, but a rise of temperature followed and he died several days after the operation. The actual source of infection was obscure. Dr. Francis Thiele, lecturer on bacteriology at the hospital, stated that experiments in connexion with anthrax had been conducted in the laboratory, and explained to the jury the possibility of a tube having been left out in error, in which case it might have been handled by the deceased. If this happened the tube might have been in a condition to require sterilisation outside, and it would, in fact, have been sterilised if the attendant had reported having found it. As he had suffered from toothache he might have touched his face and neck and infected the latter through a scratch. The jury returned a verdict of "Death by misadventure."

HOME SUMMER RESORTS.

MANY people are now turning their attention to the absorbing question where to spend their holidays. The attractions of Cardiff as a summer resort are put forth, "with the approval of the corporation," in an illustrated pamphlet by Mr. B. J. Austin Jenkins, B.A., published by the Health Resorts Association under the title "Cardiff, including Penarth and Barry." The same association also puts forth an illustrated handbook on Llandrindod Wells, edited for the urban district council by its clerk, Mr. D. C. Davies. This pamphlet deals with the amusements and recreations, the muriated, sulphur, and chalybeate springs of Llandrindod, and with other information of interest to the prospective traveller. The medical officer of health informs us that infectious diseases are practically unknown there. Also, we have received from the same association an illustrated handbook to "Deal." All these pamphlets can be obtained free on application to the Health Resorts Association, 29, John-street, Bedford-row, London. For those in search of real quiet for rest and recuperation, especially for convalescents, it would be hard to find, perhaps, a more peaceful spot than St. Margaret's Bay, between Deal and Dover, of which Mr. J. Harris Stone, M.A., writes entertainingly and well in his pamphlet, "The Piccadilly of the Sea." It is a curious little settlement on the beach of St. Margaret's Bay, sheltered from the cold winds by high chalk cliffs. It thus possesses much of the delightful and equable climate of the

Canaries; and in winter, while those at the top of the cliff are shivering in the icy blasts or shrinking in the snow, the dwellers at its foot, it is said, bask in the sun in comparative warmth and comfort without need of extra clothing. Here, within a few feet of the sea, are to be found rose gardens the products of which have taken the gold medal at the Kent Horticultural Society. Here is no rush of train, no hooting of motor, no great throng of people. Those who are seen there have business or residence there. Yet the ceaseless passing and repassing of ships in the "Piccadilly of the Sea" dispels all dulness. Mr. Stone's little book can be had for 6*d.* from the Central Publishing Co., 358, Strand, W.C. "On the East Coast" is the title of yet another attractive booklet, compiled by Percy Lindley for the Great Eastern Railway Company. It is an entertainingly written guide-book to the principal seaside resorts of the Essex, Suffolk, and Norfolk coasts. Besides many vignette engravings it contains several railway maps showing how to get from point to point, and 14 page illustrations in colours. The descriptive notices of the various places contain information as to walks, drives, hotels, boarding-houses, and house agents. A list of the Eastern Counties' golf links and of the principal fishing and yachting points in Norfolk is appended. The pamphlet can be obtained gratis on application to the Superintendent of the Great Eastern Railway, Liverpool-street Station.

CHOLERA IN MADEIRA.

IN a report on the affairs of Madeira for the year 1910 Captain James Boyle, British Consul, states that a severe epidemic of cholera broke out in November and practically paralysed trade and shipping. There can be no doubt (he writes) that as early as September—and some say before that—suspicious cases occurred, but it was not till nearly the end of November that the port was closed and the disease announced as cholera. The difficulties of medical men and others in fighting this epidemic were enormously increased and their actions much hampered by the ignorant peasantry, who really believed that the medical authorities were killing patients on purpose, and further that the various water-courses (*levadas*) were being poisoned by those interested in politics. There were two peculiar features in the epidemic. The first was the many cases and deaths among women and children, and the second was the exemption from the disease of the richer classes. This clearly points to insanitary arrangements in the poorer quarters. It is the general belief that bad water and defective drainage, &c., were the main causes, as all or most of the cases at first occurred at Funchal and its environs. The efforts of medical men and authorities in combating the epidemic were most praiseworthy, but as long as isolation in the first place is not strictly adhered to and insisted on, these diseases must spread, in spite of precautions such as the use of disinfectants, boiled drinking water, &c. According to official statistics, the number of cases during the epidemic was 1769 and of deaths 556. The population of Madeira is, roughly speaking, 150,000. It may be interesting to recall the epidemic of cholera in Madeira in 1856. It began in July and ended on Dec. 31st, and the deaths in the whole island (then having a population of 105,856) numbered 7041, showing a mortality of 6·7 per cent. It is most sincerely to be hoped that the authorities will now take in hand the long-talked-of scheme for a proper water-supply and a modern system of drainage for Funchal. This is important, not only for the inhabitants, but for the numerous visitors who flock to the island annually. Another severe epidemic is certainly possible with the water-supply in its present condition and the obsolete sanitary arrangements. If this unfortunately should happen it would have the effect of frightening away visitors and others perhaps for many years, and would cost the island far more in the long run than the public works which are so urgently needed.

FACTORY GIRLS' COUNTRY HOLIDAY FUND.

THE Rev. Canon Scott Holland has sent us a plea on behalf of the Factory Girls' Country Holiday Fund, the good work of which we have frequently extolled. Although the means for improving the health of the workers may be a matter for discussion, the need for improving the physical well-being of those who labour in our workshops and factories is thoroughly recognised, and it should be remembered that the class for which this fund provides a brief holiday in the country once a year furnishes the mothers of a large section of the population. The fund deserves wide support. Subscriptions and donations may be sent to the honorary treasurer, Mr. H. Rendell, 51, Gordon-square, London, W.C., and the Rev. Edward Canney, Chairman, St. Peter's Rectory, Saffron-hill, London, E.C.

SALVARSAN.

Messrs. Meister, Lucius and Brüning of 51, St. Mary Axe, have issued a pamphlet on "606," which they will supply without charge to any medical man applying for a copy. It gives an account of the mode of preparation of salvarsan and of its administration, and it prints reports from numerous physicians who have used it. Not the least valuable part of the pamphlet is a copious bibliography occupying nearly 50 pages.

Oxygen.—It is quite usual for both names to appear on both plates in such circumstances.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced for July and August, 1911:—

April–October.—Rome Exhibition (United Italy's Jubilee).
,, 29th–Oct. 26th (Turin).—International Exhibition.
May 3rd–Oct. 31st (Glasgow).—Scottish Exhibition.
,, 6th–Oct. 31st (Dresden).—International Hygiene Exhibition (British Section opens June 14th).
,, 12th–Oct. 31st (London, Crystal Palace).—Festival of Empire Imperial Exhibition. (Profits to King Edward VII. Hospital Fund.)
,, 18th–October 31st (London, Shepherd's Bush).—Coronation Exhibition.
,, 19th–Oct. 31st (London).—Earl's Court Exhibition.
June 1st–August 31st (Squirrels Heath, Romford).—Town Planning and Modern House and Cottage Exhibition.
July 24th–27th (Portsmouth).—British Pharmaceutical Conference.
,, 24th–28th (London).—Second International Congress of Urology.
,, 24th–29th (Belfast).—Congress of the Royal Sanitary Institute.
,, 24th–August 2nd (Belfast).—Health Exhibition in connexion with above Congress.
,, 25th–28th (Birmingham).—British Medical Association, Seventy-ninth Annual Meeting.
,, 26th (Rouen).—French National Dental Congress.
,, 26th–29th (London).—Universal Races Congress.
July 31st–Aug. 4th (Paris).—Second French Congress of Stomatology.
,, 31st–August 5th (Dijon).—Congress of the French Association for the Advancement of Sciences.
August 1st–6th (Amiens).—Twenty-first French Congress of Alienists and Neurologists.
,, 3rd–5th (London).—British Dental Association, Annual Meeting.
,, 12th–18th (Brussels).—First International Congress on Child Study.
,, 12th–30th.—E.M.I. (Enseignement Médico-mutuel International) Tour in Scandinavia.
,, 15th–21st (Dublin).—Royal Institute of Public Health.
,, 21st–23rd (Larvik).—Fourteenth Norwegian Physicians' Congress.
,, 28th–Sept. 11th (South-East of France).—Eleventh "Voyage d'Etudes Médicales."
,, 30th–Sept. 2nd (Berlin).—Third International Laryngo-Rhinological Congress.
,, 30th–Sept. 6th (Portsmouth).—British Association.
,, 31st and Sept. 1st (Vancouver).—Thirteenth Annual Meeting of the British Columbia Medical Association.

Medical Diary for the ensuing Week.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Simson: Diseases of Women.

THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn road, W.C.

TUESDAY.—3.45 P.M., Lecture:—Dr. Kingsford: Anæsthetics.

FRIDAY.—3.45 P.M., Lecture:—Mr. H. James: Mouth and Teeth.

Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. I. of 1911, which was completed with the issue of June 24th, were given in THE LANCET of July 1st.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1911 are now ready. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs. 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

Presidential Address

ON

THE PRESENT POSITION OF THE MEDICAL PROFESSION.

Delivered at the Seventy-ninth Annual Meeting of the British Medical Association,

BY ROBERT SAUNDBY, M.D., LL.D., F.R.C.P.,

PROFESSOR OF MEDICINE, UNIVERSITY OF BIRMINGHAM; AND PHYSICIAN, BIRMINGHAM GENERAL HOSPITAL.

PREVIOUS ANNUAL MEETINGS IN BIRMINGHAM.

LADIES AND GENTLEMEN,—For the fifth time Birmingham has the honour to receive the British Medical Association, and I am expressing the feeling of all classes of our citizens represented here to-night when I bid you thrice welcome to the Midland metropolis. We hope to be able to make your visit agreeable, and that you will be favoured with the fine weather upon which no small part of your enjoyment must depend; but apart from the varied entertainments and hospitalities which we beg you to accept, there is a goodly programme of business in which many of our distinguished visitors are expected to take part; and from the papers that are to be read and the discussions which have been arranged there should be much fresh food for thought—fertile material for the propagation of new and profitable ideas which will remain when the festivities of this meeting will have faded to a vista of pleasant memories. I would commend to your notice the Pathological Museum, on which much labour and learning have been lavished; it has been arranged with the especial object of illustrating a few forms of disease, a plan deemed more instructive than if we had made a miscellaneous collection of specimens ranging over a wider field; this museum is in the Pathological Department of the University in Great Charles-street. The exhibition in Bingley Hall also deserves your attention, as it comprises all that commercial enterprise can contribute to aid the art of healing, and the latest and best products of our manufacturers are there displayed.

Our meeting is this year fortunate in coinciding with the coronation of our Gracious Sovereign and Patron, King George V. We are assured that he possesses to the full measure that interest in the achievements and progress of medical science which was displayed so conspicuously by His late Majesty King Edward, and we may rely upon his sympathy and approval in all our efforts to promote the health of the people committed to his charge. We wish him perfect health to reign untroubled by foreign wars or domestic strife; we pray that he and his Gracious Consort may live to see their children grow up vigorous and honoured princes, happy in the assurance of a loyalty which is no empty sentiment, but is founded on a well-considered appreciation of the value of monarchical institutions.

I have spoken of this as the fifth occasion on which the Association has honoured Birmingham by visiting the city. At the first meeting, in the year 1834, the President, Dr. John Johnstone, devoted his address to "the great question of regulating the education of practitioners and giving the right and fixing the boundaries of practice," which was then "before the Legislature," although 24 years had to pass ere such a project of law became embodied in an Act of Parliament. It is interesting to know he could think that the problem of medical education, "as society is at present constituted, presents no difficulty." He regarded the existing opportunities for academical teaching as "quite sufficient," as medical studies should be confined to anatomy, physiology, pathology, and natural philosophy. But, however much this may come short of our modern ideal, we may heartily agree with him when he says that "character, after all, must be the foundation upon which any system of medical education is built," and for that we must rely chiefly upon the training given during those impressionable years devoted to preliminary education, "which should consist of classical instruction, combined with a wide range of moral and religious teaching," these being the "best groundwork of future judgment and higher intellect."

In 1856 the presidential address was given by Dr. James Johnstone; it was brief, and dealt chiefly with the need for sanitary reforms, which he urged upon the Association, insisting that such a body could effect a great deal of good by advocating them. It is satisfactory to remember that to this Association in no small measure is due the adoption by Parliament of those sanitary measures by which the health of the people has been so greatly benefited.

At the meeting in 1872 Mr. Alfred Baker devoted his address to the same topic, and pleaded that a city such as Birmingham should possess those powers of town planning which, after the lapse of 38 years, have at last been granted. Although we may congratulate ourselves upon many improvements in the sanitary condition of Birmingham, I regret that we cannot at present say with truth, as he did, that "fine and healthy trout are frequently taken by the angler in the Tame at Hamstead," near Birmingham, for the pollution of our rivers, which is a great national misfortune, has increased as a consequence of the presence of a great population on their banks.

MEDICAL EDUCATION.

At the last meeting, in 1890, Sir Willoughby Wade reverted to the subject of medical education. He insisted that the time devoted to the numerous branches of medical education was too short, that cramming took the place of study, and that the true purpose of education was lost. He would not propose to lengthen the curriculum, as that would involve an increase in cost which would press too hardly upon the resources of the average student, but he desired to get rid of some of the subjects at present included, defending himself against the accusation of desiring "to lower the standard of medical education," which, he said, was a phrase more deadly than any argument. He contended that "the question to ask is not what the student has learnt, but how he has learnt it; not how much knowledge he has acquired, but whether he understands what he has been taught; not what he has thought about it, but whether he has learnt to think at all"; and he ended a striking address by the warning—*Propter scientiam sciendi perdere causas.*

The editorial article in the *British Medical Journal* which dealt with this address pointed out that at the commencement of his medical career the student who is fresh from school, untrained in the habit of teaching himself, is obliged to face "some of the toughest and driest subjects" in the whole curriculum, and it compared our course of studies to a cone of which the broad instead of the narrow end is presented to the neophyte. Under the old plan of medical education, as we read in the biographies of Sir James Paget and Sir William Broadbent, a lad on leaving school went as a pupil to a medical practitioner, where he learnt something about the general routine of practice, and grew familiar with the atmosphere of the profession, and thus was more or less prepared for his work when he joined a medical school; on the other hand, his general education too often suffered, and, while there was much that was good in the old system, it has passed away, and no useful purpose can be served by trying to set back the clock.

When 16 years ago the curriculum was extended to five years it was hoped that the student would have more time to devote to the strictly professional part of his education, but the extra year has been swallowed up by the increased demand of the teachers of the preliminary sciences. We are again complaining that the time is too short, and this can hardly be doubted in the face of the fact that the majority of students fail to obtain their qualifications in six years. Some think that preliminary science, or at least elementary chemistry, physics, and biology, should be learnt and passed before the student enters upon his medical studies, and as these subjects are now adequately taught at many of our public schools it is better to leave boys for another year under school discipline and instruction than to launch them at so early an age into a medical school, where the supervision of studies and the control of conduct must necessarily be comparatively weak, where temptations to idleness are many, and where too often the lad is removed from the guidance of master or parent and lives alone in a great city surrounded by sources of pleasure which are irresistible to his inexperienced mind and unformed character. What wonder is it if under these conditions the first year is often wasted? No parent would

willingly expose his son to such risks, but the supposed obligation to enter him at a medical school as soon as he has passed the preliminary examination, in order that the year may count towards the curriculum, outweighs his scruples. For this we must blame the regulations of the General Medical Council and of some of the qualifying bodies. But the Council has recently modified its rules, and as some of the most important bodies now recognise the instruction given in properly equipped secondary schools, it is to be hoped that their example will be generally followed. It should be possible to make the curriculum five years in a medical school after preliminary science has been passed, and so adequate time be obtained for those subjects which can be learnt only in a medical school and in hospital.

Though there is still much in the modern arrangements for medical education which falls short of our desires, there has been a vast improvement in the organisation of medical teaching, in the equipment of medical schools, and in their methods of instruction. Of these not the least important is the foundation of this and other provincial universities, for which large sums of money have been subscribed by the public and to which the Education Department recognises its obligation to render financial assistance in the national work they are doing. Medical education in England has always had its feet firmly planted on the solid foundation of hospital work, but it was deficient in academical opportunities as compared with the schools of Scotland and the Continent, and while these steadily improved their clinical teaching we for a long time hardly realised our deficiencies. Our numerous and admirable hospitals have provided abundant clinical material, and many subordinate appointments of incalculable value for the training of practitioners, but the scientific needs of students are but poorly supplied in them. During the last 10 years this has been to some extent remedied by the better equipment of our medical schools, mainly by the self-sacrifice of the senior teachers, who have surrendered the greater part of their scanty emoluments for this purpose; laboratories have been started in all our schools, and in some hospitals it has been realised that it is not enough to possess good accommodation for the care and comfort of the sick, but that adequate means must also be provided for the study of their diseases by good laboratories with a sufficient paid staff. We in Birmingham who work in the hospitals or in private practice are indebted to our colleagues at the University for much assistance which is exerting an incalculable influence on the character of medical practice, but I would plead with our hospital authorities to take a broader view of their duties and to realise that in the end the interest of the patients will be best served by spending more money on the scientific equipment of these institutions.

THE FUNCTION OF VOLUNTARY HOSPITALS.

We in Birmingham are justly proud of our hospitals, which have been to a large extent rebuilt or reorganised since the Association last visited this city. Several of them are in their way model institutions, and we hope you will visit them, for which arrangements have been made. Supplemented as they are by municipal hospitals for the reception of infectious diseases, it may be fairly claimed that they provide assistance for all the pathological evils to which our flesh is heir; and if they are never equal to the demands made upon them, we must remember that Birmingham is a metropolis which draws patients from a population exceeding by far that of the so-called Greater Birmingham, which after all only includes our own suburbs. Hospitals are burdened with work which is largely of an unnecessary kind; each maintains an overcrowded out-patient department, easy if not absolutely free of access, where relief is given to all who ask for it however trivial their ailments, although some sort of check is attempted to exclude unsuitable cases by the appointment of inquiry officers and similar means. Hospitals boards and medical staffs recognise the evil of our out-patient system and desire to find a remedy, but with all the goodwill in the world this is not so easy as it may seem. The out-patient system has grown up in comparatively recent times and in response to an irresistible public demand. It was certainly not created or encouraged by the honorary staffs, which in Birmingham 40 years ago left the work mainly to the resident officers. As this was not satisfactory, assistant physicians and assistant surgeons were appointed to take charge of the out-patients, and the great expansion of the department dates from that time. That this is not peculiar to Birmingham is shown by the case of the Liverpool Royal Infirmary, which had only a small out-patient hall when it was rebuilt about 20 years ago, but within the last 12 months has found it necessary to open a large additional building for this purpose. At the Edinburgh Royal Infirmary in the "seventies" the only out-patients were those who attended for consultation and who received no medicine, but merely letters to their doctors or prescriptions and advice. Accidents and minor surgical cases were seen, but there was nothing that corresponded to an out-patient department, such as I understand has grown up during recent years.

Dr. Lauriston Shaw holds that hospitals should provide for the poorer classes of the community just that additional assistance which a member of the wealthier classes under the care of a general practitioner is in the habit of obtaining from a consulting physician or a consulting surgeon whenever special treatment or advice becomes necessary. He regrets that hospitals have laid themselves out to provide simple medical and surgical treatment for all comers. I agree with him in deploring it, but I recognise that the out-patient departments have developed in response to a demand which the hospitals, as dependents on public goodwill for their incomes, were not in a position to refuse. Moreover, in the absence of any well-organised system of medical attendance on the poor by dispensaries, or by such methods as may be developed under the scheme of National Insurance, the hospitals cannot repudiate this burden without exposing themselves to a charge of inhumanity. Yet a change that would permit the hospitals to follow the plan described by Dr. Shaw would be welcome, as it would promote their efficiency by setting them free to devote all their resources to the more serious cases.

Mr. J. Courtney Buchanan, in his paper on the Function of the Voluntary Hospitals in relation to the proposed Public Assistance Authority, has advocated the limitation of the work of the voluntary hospitals by excluding not only those cases, such as fits and insanity, which are usually regarded as unsuitable, but also the very poor and the well-to-do. He considers that all patients should pay something towards the cost of their treatment and maintenance in the hospital in proportion to their means; if unable to do this they come into the pauper class and should be treated by the Public Assistance Authority. He would reserve hospitals for acute, costly, or special cases. In order to meet the objection that this would diminish the clinical value of the voluntary hospitals he considers that the Poor-law hospitals should be open under proper regulation to medical students. The out-patient departments of general hospitals should be reserved for consultation cases, the ordinary out-patient class being treated in provident dispensaries or dispensaries provided by the public assistance. At these consultative out-patient departments the number of cases to be seen by each consultant should be limited. He accepts the provident dispensary plan outlined in the report of the Majority of the Poor-law Commission, by which the dispensaries would be staffed by all those medical practitioners residing in the district who are willing to undertake the work, giving the patients the right of selection. He does not think much importance need be attached to the objection of the Minority, that free choice would mean that doctors would seek to gain popularity by being liberal with extras, as this, he says, would be checked by a system of supervision and inspection, with power to remove from the panel the name of a doctor whose conduct is not satisfactory. Another of his suggestions is that no out-patient should be seen a second time without bringing a card signed by a general practitioner; but although this might be useful to rid the hospital of trivial or unsuitable cases, where the case required to be seen a second time, no hospital officer would run the risk of failure to obtain the necessary signature, but would tell the patient to come a second time, whether the signature was obtained or not. A further suggestion is that the hospitals and dispensaries should be supported by a rate levied on the class likely to use them; the obvious objection to this is that this class pays no rates, so that the money raised would come out of the pockets of the owners of small house property or lead to an augmentation of rents which are already too high.

Mr. Charles Booth also thinks voluntary hospitals should limit the work they wish to undertake, instead of, as at

present, taking all that comes, much of it being of a kind that they do not want, and thus finding a hindrance in doing the work they are specially adapted to perform. If their work were so limited on the Poor-law would fall the duty of providing for these cases rejected by charity. He points out that the proposal to put the treatment of all sickness under the health authority presupposes that it must be not only free but compulsory, but if so "it postulates an exactitude of medical diagnosis and a finality of treatment which have not yet been attained, as well as a degree of discipline and of sacrifice of liberty as yet unthought of," nor does he believe that in practice it would be possible to recover payment in proportion to means, as suggested in the Minority Report of the Poor-law Commission. He concludes that there would be a residue of paupers to be dealt with by the Poor-law—that is to say, there would always be chronic destitute sick who would not be kept permanently in any voluntary institution, and would have ultimately to go to a Poor-law hospital, and he thinks that, as the Poor-law would have to undertake the care of these people who would not come properly under the health authority, there is no reason for refusing to allow the Poor-law authority to deal with acute cases of illness in destitute persons.

I am quite in agreement with the view that voluntary hospitals should define their work and give up the attempt to deal with all cases of sickness that enter their doors. During recent years they have declined to deal with infectious cases, and provision has been made for these by the sanitary authority; it remains for the hospital authorities to refuse to treat urgent but trivial cases, and to reserve their institutions for serious cases of a medical or surgical kind, for special diseases, and, above all, for cases referred for diagnosis or treatment by medical practitioners.

MEDICINE AND THE STATE.

It is part of the programme of the International Social Democratic Party that the State should undertake the entire control of health services, and therewith the practice of medicine, so that in the "State of the Future" the fate of the doctors is sealed. Without wishing to exaggerate this fact, it must not be forgotten that there are some practical men having no sympathy with socialistic dreams, who yet desire to see the medical profession made a service of the State, and among them are even members of the medical profession. Their usual argument is that there is a conflict between the interests of the medical profession and the public health which can only be removed by subsidising it and making its business to be to prevent rather than to cure disease. But while a State medical service is admissible and even desirable for administrative and sanitary purposes, a compulsory absorption by the State of all medical practitioners would not be in the interests of the public, of the profession, or of medical science. If medical practitioners are to be in the service of the State they must be given the power to compel submission to treatment, a condition which would lead to the most extraordinary abuses, while the calling of a medical practitioner would be of all the most miserable. In South Switzerland such an experiment came rapidly to grief; in Bellinzona 55 practitioners accepted fixed salaries to attend both rich and poor, the town and its suburbs being divided into districts, the inhabitants of which paid a small tax for medical treatment; of the 55 doctors at the end of 18 months 53 had come to the conclusion that they could not continue the arrangement, as the demands of the public by night and by day could not be satisfied. Moreover, it must be remembered that doctors are only human, and that human nature has its inherent weaknesses. State doctors would be deficient in diligence and ability, and the "Government Stroke" would be seen in their work so soon as the stimulus of free competition was removed.

At the present time we are threatened with dangers created by proposed social legislation whose bearings it is impossible to foresee, but which are sufficiently serious to justify the distrust with which it is regarded by all classes in the profession. Medical attendance on the poor has been provided by: (1) the Poor-law; (2) charitable hospitals and dispensaries; (3) provident dispensaries; and (4) medical clubs. The first has been the subject of severe criticism, but its worst features are due to the fact that it is generally ill-paid contract work, the better plan being, wherever possible, to give it to whole-time officers who are paid an adequate salary. What has been already said about hospitals applies to dispensaries, as both should be used only for consultations in grave or obscure cases, or for those needing special treatment. Provident dispensaries exist in many towns, but are often regarded with suspicion on account of the unwillingness of their managers to impose a wage limit. Clubs are of many kinds, of which the simplest are those established by individual practitioners, who undertake to give all necessary medical attendance in return for a small annual payment. These are common in country districts and are distinctly beneficial, as the doctor, who would otherwise receive nothing, gets a small payment, while the patient retains his self-respect. As the doctor controls the admission of members, he runs no risk of the club being abused by persons whose circumstances do not justify the concession. Clubs which exist in connexion with works and collieries are generally controlled by the management and not by the men, and their relations with the medical profession are usually satisfactory. It is where medical attendance is provided by insurance societies, medical aid societies, or friendly societies, which seek to make a profit out of this part of their work or to use it as a means of attracting subscribers for their other benefits, that the profession has had most cause to quarrel, so that the Battle of the Clubs has become a familiar headline in the medical press. In 1892 the General Medical Council appointed a committee to inquire into the working of this system, and in 1893 a report was issued, together with a considerable amount of evidence, to prove there was good ground for the dissatisfaction of the profession. The conclusions of the report showed that the evils of which complaint had been made, and which were proved to exist, were the excessive number of patients, causing "great exhaustion and disheartenment to the medical officer," and to the patients' impossibility of obtaining adequate treatment; the abuse of these clubs by persons whose means and social position gave them no claim to be treated on reduced terms; and, lastly, the dependent position of the medical officers, which was inconsistent with the conscientious performance of their duties.

When medical practitioners were allowed to employ unqualified assistants contract work could be performed at least profitably if not efficiently; but in 1897 the General Medical Council, with the hearty approval of the medical profession, insisted that all patients must be seen by qualified practitioners, and the club doctor has since that time been compelled to do the work himself or to employ an expensive qualified assistant. This undoubted reform meant a great improvement in the quality of the medical attendance given to the working classes, and ought to have been accompanied by an increase in the rate of payment, but the legitimate demands of the medical profession were set aside, and as no efficient organisation existed, the result has been a long-drawn-out quarrel and widespread discontent on the part of the medical profession with the club system. The rate of payment is so low that to earn a sufficient income more work is undertaken than can be properly accomplished. The overworked doctor sees his patients hurriedly and falls into a routine method of treatment; he loses interest in his work; the bright ideals with which he started in practice fade away, and when he has time to reflect he feels ashamed of himself and angry at the bondage from which he would gladly escape. That this is a true picture of many a club doctor no one who knows the medical profession can doubt, nor should any one be surprised that the prospect of an enormous increase of this system under the control of the friendly societies fills us with dismay. Such work is not only degrading to the doctor but is bad for the patient, and if custom made some of us blind to its evils, the prospect of having under the National Insurance Law to attend a third of the population on these terms has roused a spirit of resistance which will not be satisfied by rejecting the new proposals, but aims at getting rid of the burden which has galled us for so many years. In this effort we ask for the sympathy and support of the public. The services of a medical practitioner are above all others difficult to appraise, but no one can doubt that they cannot be adequately rendered if he is unable to spare the necessary time to examine his cases. What can be the good of spending millions on the provision of sanatoriums for phthisis

if the medical attendance is to be of such a character that early cases will rarely be recognised? The interests of the public are at one with those of the medical profession in the need for putting an end to contract work. The only argument in its favour is its cheapness, but if it is true that the health of the people is the greatest national asset, we cannot tamper with the efficiency of the medical treatment to be provided. To secure this it is essential that the duty of providing medical benefits should not be entrusted to friendly societies or insurance companies, and that the doctor should be paid for his work and not asked to undertake a contract of which no one knows the risk. The former of these conditions has been admitted to be desirable by the Chancellor of the Exchequer himself, and although it is resisted by the friendly societies, it is to be hoped that Parliament will recognise the need for granting it. But we are told that the second is impossible, because as no one can calculate the risk, and as the funds to be provided under the Act are limited, it is necessary to impose the burden, not upon the general taxpayer, but upon the medical profession! When the proposal is stated in plain language it seems hardly possible that Parliament can be asked to sanction anything so manifestly inequitable. We are told that if the doctor would benefit from the patient's fraud there would be no check on malingering, to which the answer is that in this matter you must trust the medical profession, and the way to make doctors faithful guardians of the public interest is to treat them fairly. Any medical man convicted of conniving at malingering can be made liable to be removed from the panel of practitioners employable under the Act, and you may be sure that there will be a sharp look-out kept by the profession to check such practices. The third objection is somewhat similar, as it is feared the doctor would unduly prolong his attendance, and the answer is the same, but Parliament and the public should know that the National Deposit Friendly Society has for years conducted its business on the principle of paying the doctor for work done, and has not had to complain of the result.

THE NATIONAL INSURANCE BILL.

The National Insurance Bill is admittedly an adaptation of the German law of 1885, and a Parliamentary paper has been circulated (Cd. 5679) containing the opinions of various authorities in Germany in support of the proposed legislation. With equal reason we may look to Germany for warnings and danger signals, and I would point out that the effect of placing the administration of medical benefits in Germany in the hands of committees controlled by working men has been to cause a bitter quarrel between the two parties, and has led to the formation in Germany of a medical organisation with a membership of 21,210, known as the Leipzig Union (*Leipziger Verband*). Its object is to meet organisation by organisation, to create a fund for fighting purposes, and to form a league for conducting an agitation in the event of any action on the part of the societies contrary to the interests of the medical profession. It is, in fact, a trades union founded on the same lines and having similar objects to those of the workmen, and ready to use the same means—namely, a strike, to gain its end. Our German colleagues claim that although this has been said to be unworthy of a liberal profession, it is the necessary outcome of the situation created by Parliament, which has sought to benefit the wage-earners at the expense of the medical profession. So far the Leipzig Union has been victorious in all the contests in which it has been engaged, the best part of the medical profession having rallied absolutely under the banner of professional union. Those who have remained outside are only army doctors, university teachers of theoretical subjects, doctors without practice, and a few cautious medical bureaucrats; and no one knows better than the leaders of the workmen's societies and the directors of the insurance companies that they must rely only upon the most incapable medical aid should they quarrel with the medical profession.

What has been done in Germany can be done here. If Parliament forces a fight upon us we are not unorganised. The British Medical Association, which was founded with quite other objects, has been compelled by the militant tactics of the Friendly Societies and clubs to create a department for the defence of medical interests, and this is conducted with great ability by the medical secretary, Mr. J. Smith Whitaker. During the past year, and owing to the threatened danger, over 3000 new members have joined our ranks, and approximately we number to-day 24,400 members. Without the medical profession the Insurance Act must fail, and I think these numbers justify me in saying that it cannot succeed without the British Medical Association. As all parties in the House of Commons have accepted the principle of the National Insurance Bill, and even the medical profession has accorded a welcome to a measure which proposes to make better provision for the care and maintenance of the sick poor, criticism of it is difficult, yet the experience of Germany and that of those who are well acquainted with the conditions and opinions of our own poor, and of the working of our national institutions which have for so many years striven to help them, should make us hesitate to adopt without careful consideration in all its details a scheme which proposes to revolutionise the relations of the wage-earning classes to the State, to their employers, to the medical profession, and to those charitable institutions to which they must continue to look for help in many serious illnesses.

It is a mistake to suppose that there is any legitimate comparison between the condition of Germany in 1885 and that of this country in 1911. The voluntary principle has been sufficient to provide us with a system of hospitals and dispensaries which is on the whole superior to that of Germany, except in the one department of sanatoriums for tuberculosis, and even here our shortcomings have been exaggerated. Mr. W. H. Dawson claims that Germany has provided 7294 beds for the treatment of tuberculosis, while in England, according to the estimate of the secretary of the National Association for the Prevention of Consumption, we have about 2500 beds; but our population is only half that of Germany, and a comparison of the death-rate from consumption in the two countries warrants the belief that the prevalence of tuberculosis here is only two-thirds of that in Germany. If allowance be made for these facts, 2500 beds constitute nearly as adequate a provision as that existing in Germany. Under these circumstances it is extravagant to provide such a large sum of money for building and maintaining sanatoriums, and unwise to neglect to set aside any funds for the treatment of the numerous special cases that must arise, and of which I fear it is proposed to cast the responsibility upon the voluntary hospitals, whose sources of income have already been sapped by the heavy estate duties, and are further threatened by the taxation under this Bill, which will fall upon the employers and workpeople who at present contribute a share of the incomes of the hospitals in this district which appears to range from 30 to 90 per cent.

How long the friendly societies, which afford a splendid example of national thrift, will survive side by side with the compulsory principle remains to be seen, but it is at least to be hoped we shall avoid the danger of allowing them to become the controlling power in the scheme. In Germany the workpeople have managed to gain this position, and the principal amendments to the German law which have been passed by the Reichstag during the summer have been directed to diminishing the influence of the workpeople on the various committees and preventing the bureaus from being used for political purposes. It is believed that Socialist officials and doctors have been appointed regardless of their qualifications for office, that the distribution of printing and advertisements has been confined to Socialist newspapers, that money has been improperly spent for the purpose of Socialist literature, while paid officials have been permitted to act as Socialist agitators. This is the result of a measure which was advocated by Bismarck as the best means of checking the growth of Socialism! Not only has it failed to do this, but it is also said to have become a corrupting influence which is sapping the honesty and independence of the German people. No one has ventured to impugn the competence and impartiality of Dr. Ferdinand Friedenburg, a lawyer and ex-President of the Imperial Insurance Bureau at Breslau, who, in an article published last April, has made this charge against the Insurance Law. He complains of its extravagant management, of the endless litigation to which it has led, of undue pressure being brought to bear on magistrates and medical practitioners to induce them to give decisions favourable to the workpeople, of excessive compensation, of laxity in interpreting the law, and of the enormous increase in the number of claims which from 100,159 in 1886 rose to 662,231 in 1908. In his opinion it

has led to general demoralisation among the classes concerned; claimants magnify slight injuries, neglect prescribed treatment, keep wounds open by artificial means, or remove or spoil apparatus, and then represent that it has done harm. He points out that the position of the doctors is peculiarly difficult, as they stand between the insured and the insurance board, and every claim must depend upon medical support. The consequence is that a doctor known to be lenient is sure of a large practice, while one who tries to do his duty is boycotted and driven out of practice, and he gives instances of cases within his own knowledge in support of these charges. But we need not look to Germany alone to find ground for mistrusting the effect of this legislation. Miss Loane, whose work amongst the poor gives her the right to express an opinion, is convinced that compulsory insurance will not be regarded by them as a benefit. She says that they fail to understand the principle of insurance, and often account themselves wronged if no illness occur to enable them to make a claim on their club, while the sight of a neighbour benefiting by insurance increases their unwillingness to join or to continue to subscribe, because they see that the sick man is drawing their money, and if the club were the State she thinks the practical results would be no better. Even voluntary insurance, if the result of over-persuasion, gives rise to most unbounded claims, and commonly results in bitter discontent. She tells of a young woman who was induced to pay 2*s.* a year for three years, for which she enjoyed ten weeks at a seaside convalescent home, besides various small privileges. Her mother was deeply dissatisfied with this return for her money. Again and again she said: "T'ain't as if she 'asn't paid for it; three years on end she has been paying in regular. I don't call that no charity!" If these are the results for which we are destroying the voluntary principle and establishing compulsory thrift in its place, we may well doubt whether future generations will be so grateful to our present legislators as they would doubtless wish.

I regret that I have been obliged to refer to political matters in this address, but this is not a party question, and the medical profession is not divided about it. Silence on my part would have been misunderstood, and if I have succeeded in defining our position and in making clear what we desire, and why we do so, I shall have attained the object I had in view.

Address in Medicine

ON

MISTAKES.

Delivered at the Seventy-ninth Annual Meeting of the British Medical Association

BY BYROM BRAMWELL, M.D., P.R.C.P. EDIN., F.R.S.E.,

SENIOR ORDINARY PHYSICIAN, EDINBURGH ROYAL INFIRMARY; LECTURER ON PRINCIPLES AND PRACTICE OF MEDICINE, EXTRA-ACADEMICAL SCHOOL OF MEDICINE, EDINBURGH.

MR. PRESIDENT, LADIES, AND GENTLEMEN,—Allow me, in the first place, to express my thanks—my very sincere thanks—to the Council of the Association for the honour it has conferred upon me in asking me to give this address. The feeling of pleasure and satisfaction which I experienced on receiving the request of the Council was, I need hardly say, qualified by a feeling of apprehension when I realised how difficult it would be to follow satisfactorily in the footsteps of the long roll of distinguished men who have preceded me in this honourable position, and how difficult it is to fix upon a suitable subject for one's remarks. While thinking over likely subjects—some scientific, some of general interest—I asked Dr. William Collier, when we were examining together at the Army Medical College in January last, what he would suggest. Dr. Collier thought that as the great majority of the audience would be general practitioners, a practical subject would be much more acceptable than an elaborate discussion on a scientific or technical subject; he thought one of the most interesting and instructive subjects, in the hands of a man of wide clinical experience, would be Mistakes. Well, that being so, it seemed to me that mistakes was a subject with which I was well qualified to deal, for I have had a large and varied clinical experience and—I have made many mistakes.

It is hardly necessary to say that it is not a question of who makes and who does not make mistakes; it is only a question of who makes the most mistakes and the biggest mistakes. The most experienced of us, who make a point of checking our clinical observations and diagnoses by post-mortem examinations whenever it is possible to do so, will I am sure, admit that we make many mistakes. Nor can this be wondered at when one remembers the extent of modern medicine and the impossibility of any one man mastering it as a whole and making himself practically familiar with each of its individual parts in detail; the extreme complexity of many of the problems with which the physician has to deal; the elaborate and highly technical nature of some of the chemical, instrumental, and other methods of clinical examination and research which we employ; the insufficient data on which we have sometimes to found our opinions; the great difficulty we often have in eliciting and observing the facts; the circumstance that in some cases we have to rely upon the statements and observations of the patient or his friends for some of the data on which our opinions have to be based, and that those statements and observations are often inaccurate and sometimes positively misleading; and the natural imperfections which are inherent in every human mind.

But there are mistakes of various kinds. There are the bad mistakes which show incapacity to make the most ordinary observations, gross ignorance, or inexcusable carelessness; and there are the slight mistakes—they perhaps should hardly be called mistakes—such as erroneous conclusions with regard to the significance of certain facts or groups of facts. There are mistakes of omission and mistakes of commission, mistakes due to incomplete, inaccurate, or erroneous observation, mistakes due to hasty or illogical conclusions. There are mistakes which as regards their results are unimportant; and mistakes which, either to the practitioner who makes them, to the patient whose case is wrongly diagnosed, or to the public at large, are of great importance, since they may entail very disastrous consequences.

Everyone will allow that one learns from one's mistakes, and that when one does make a mistake, one should always try to analyse it and find out the cause of that mistake.

IMPERFECT KNOWLEDGE.

Mistakes due to imperfect knowledge, to want of clinical experience, to erroneous observation, to inability to observe correctly, are most common in the early years of one's practice. Let me mention one or two mistakes of this kind, for the details of concrete cases, which have actually occurred in one's own practice, make far more impression on the mind of one's audience than mere statements of fact as regards differential diagnosis.

Hæmoptysis due to mitral stenosis mistaken for phthisis.—Soon after I entered practice a young man came to me complaining of cough and spitting of blood. He was a thin, weedy individual of poor physique; several of the members of his family, I knew, had died from phthisis; bronchitic râles and moist sounds were present over the apices of the lungs. Without examining the heart I diagnosed phthisis. Some little time afterwards he consulted the late Dr. Murchison, who found that he had mitral stenosis and that he was not suffering from phthisis. Since then I have never failed to examine the heart in all cases of hæmoptysis.

Hæmorrhagic small-pox mistaken for typhus fever.—About the same time I was called to see a well-to-do old gentleman living in eminently satisfactory surroundings. His illness was of two days' duration. It had commenced with headache, backache, and vomiting. He was feverish; the lower part of his abdomen and adjacent parts of the inner side of the thighs were covered with a profuse, confluent, plum-coloured, purpuric rash; his conjunctivæ were suffused with blood; he was vomiting blood and passing blood by the bowel and kidney. He rapidly became comatose, and died before the consultation which had been arranged with the late Dr. Charlton of Newcastle came off. I certified his death as due to typhus. The diagnosis was much criticised. There was no typhus, and for years there had been no typhus, in the place—North Shields. Subsequent inquiry and consideration showed that

the case was one of malignant small-pox. The old gentleman—a shipowner—was in the habit of visiting his retired ship captains. In the house of one of them, who lived in Newcastle, and whom he had visited about a fortnight before the commencement of his illness, there was a case of small-pox. There was no small-pox in North Shields at the time. Soon afterwards we had a severe epidemic, during which I saw more than one case in which the remarkable initial purpuric rash over the bathing-drawer area and adjacent part of the thighs, which was such a striking feature in the old gentleman's case, was present.

Pain in the back due to the pressure of an aortic aneurysm.—A full-blooded, robust-looking man came to me complaining of a fixed pain between the shoulders. I could not detect anything abnormal; and, relying too much on my powers of physical examination (as the young practitioner who has just qualified is apt to do) I ignored the symptom, the patient's suffering, and told him that there was nothing of consequence the matter with him. Shortly afterwards he died suddenly. Post-mortem examination showed an aneurysm of the descending thoracic aorta, which had ruptured into the pleural cavity. Since then I have never disregarded a fixed pain in the back in an aneurysmal-like subject, and I have always tried to give due weight to the patient's symptoms and complaints.

But while, as this case proves, mistakes may result from ignoring or making too light of the symptoms and complaints of patients, the remarkable absence of symptoms in some cases of advanced organic disease shows that the *only way to avoid mistakes of omission is to make a complete physical examination in every case which comes before us.* The following case illustrates this point.

Enormous aneurysm of the thoracic aorta: no symptoms.—A man, aged 58, who had worked for two years at the Forth Bridge during its construction, first as a fitter, afterwards in looking after the planing machine, neither of which is heavy or severe work, received a blow on the right eye on March 9th, 1885. On admission to the Edinburgh Royal Infirmary the lens was found in the anterior chamber. It was removed by the late Dr. Argyll Robertson the following day. On the evening of March 14th he had a severe attack of dyspnœa. Physical examination showed extensive dulness and heaving pulsation over the upper part of the front of the chest. He died suddenly the following day in consequence of the rupture of an aneurysm into the left pleura. Now, up to the date of the accident this man had never been off work for a single day, had never consulted the doctor gratuitously provided for the employees at the Forth Bridge, and had never made any complaint to his fellow workmen. The case is remarkable, for, in addition to this enormous fusiform aneurysm—I think it is the largest intrathoracic aneurysm I have ever seen—the trachea was directly pressed upon and flattened by a small secondary sac.

HURRY AND HASTY CONCLUSIONS.

In the case of experienced practitioners, *hurry, and the incomplete examination of patients due to hurry, and hasty conclusions* are probably by far the most common causes of errors in diagnosis. Physiognomic diagnoses, I need not say, are apt to be erroneous. Some of you have, no doubt, heard the story of the professor who prided himself on his powers of physiognomic diagnosis, and the patient with gouty, *but artificial*, teeth.

INACCURATE INFORMATION.

Mistakes are not infrequently due to the fact that *the information which we get from third parties is insufficient, inaccurate, or misleading.*

Suspected Addison's disease.—A pitman came to me complaining of loss of strength and weight, which he said had followed an attack of influenza. I could detect no physical signs of disease to account for the extreme asthenia and marked emaciation. His hands and face were deeply pigmented, but for some weeks after the influenza he had been sitting out in the sun. The skin of his back was, I thought, a little dark. Thinking that the case was probably one of Addison's disease, I was anxious to get further information on the point, and told my house physician to bring in the patient's wife. On asking her whether she thought the patient's skin was darker than it had been before the attack of influenza she answered, "I could not say." I then told her to look at the patient's back and tell me whether she thought it was darker. She said, "I could not say; I never saw his back before." I then said, "That is a remarkable statement. Do you mean to tell me that you never saw your husband's bare back before?" She then said, with some show of indignation, "He is not my man at all!" It appeared that the house physician had brought in the wrong woman. Now if the information available had stopped here a mistake of omission might easily have occurred; but fortunately the real wife was available; she thought that the skin was darker. The patient died a few days later, and the diagnosis of Addison's disease was confirmed.

Functional spasm.—In January, 1910, I published in my *Clinical Studies* an interesting case of spasmodic muscular contractions in which the symptoms disappeared rapidly and completely under isolation and psycho-therapeutics. The doctor who sent the patient to me had diagnosed the case as Thomsen's disease; he wrote me saying that the patient had been in the Cardiff Infirmary, where the same view had been taken of the case, and where the patient had not improved. In commenting on the case I quoted these statements, not with the object of reflecting in any way on the diagnosis, but for the purpose of showing how closely in some of its features the case resembled Thomsen's disease. Some 15 months after the case was published I received a letter from the physician under whose care the patient had been saying that he *had not* diagnosed the case as Thomsen's disease, and that the patient *had* improved in the Cardiff Infirmary, and asking me to contradict my statements. I am glad to take this opportunity of putting the matter right, and correcting the, but not my, mistake.

The importance of verifying one's facts before giving an opinion was forcibly brought home to me by the following case. I once asked an old lady, for whom I had prescribed a few days previously, how she was feeling. She replied, "Very much better, thank you, I am almost quite well again." I then said, "I was sure *that* medicine would do you good." The patient smiled and said dryly, "But, doctor, I did not take it." I need hardly say I felt "very small." I learnt by that mistake.

UNDESCRIBED DISEASES.

Before a disease is described as a distinct clinical and pathological entity, typical and characteristic cases, which a few years later are easily diagnosed, are mistaken for other conditions; after the disease has been recognised and described one wonders how one could possibly have made such mistakes.

Myxœdema is a striking illustration in point. The appearance of typical cases of myxœdema is so characteristic that one can with certainty recognise them at a glance. But until the late Sir William Gull published his description of the clinical features of the disease in 1874, cases of myxœdema were generally diagnosed as cases of Bright's disease or obesity. That some observers were well aware that the condition was a peculiar one I know from my own experience; for when I entered practice in the year 1869 my father showed me a splendid example of the disease, directed my attention to many of the characteristic clinical features, and told me that he believed the condition was a new disease—a disease which had never been described.

Myasthenia gravis is another excellent illustration. I remember when in general practice being much puzzled by the case of a young woman supposed to be suffering from hysteria; she died suddenly with bulbar symptoms. Post-mortem examination revealed nothing to account for the death. I now know that it was a case of myasthenia gravis.

ERRONEOUS DEDUCTIONS.

Mistakes due to *erroneous deductions and illogical conclusions* are very common. Nor is this to be wondered at when it is remembered that there is probably no faculty of the human mind which differs more in different individuals than the faculty of judgment—the power of seeing things in their correct proportion, the ability to weigh correctly all the facts of a case and to draw the correct and logical conclusion from them. Even those men in whom the judicial faculties are most highly cultivated often fail to draw the same conclusions from the same facts. How frequently we see the judges differing on points of law, and the opinions and decisions of the lower courts reversed in the Court of Appeal and in the House of Lords! Now, if this occurs in law, how much more likely is it to occur in medicine; for, in comparison with medicine,

law may be almost regarded as a fixed science. Further, in medicine the facts on which our conclusions and opinions have to be based are, in many cases, very difficult to observe, and, in some cases, chiefly or entirely consist of the subjective sensations described by patients.

Mistakes in diagnosis often occur because *undue importance is given to some symptom or physical sign* which is present. Take, for example, *double optic neuritis*. In many cases in which the diagnosis lies between an intracranial tumour and some of the other conditions with which it is apt to be confounded, the presence of double optic neuritis decides the point in favour of tumour, and the absence of double optic neuritis is a cause of doubt. On the other hand, the presence of double optic neuritis may suggest a diagnosis of tumour when no tumour is present. The differential diagnosis of tumour of the frontal lobe and general paralysis of the insane is sometimes attended with great difficulty.

Now, double optic neuritis, which is so common in cases of intracranial tumour, is very rare in cases of general paralysis of the insane; consequently, if double optic neuritis happens to be present in a case of general paralysis of the insane, in which the diagnosis lies between general paralysis of the insane and frontal tumour, the diagnosis is very likely to be erroneous. The same statement applies, though with much less force, to localised tenderness on skull percussion.

Again, take *hunger pain, the presence or absence of free hydrochloric acid in the gastric contents, and hæmatemesis.* A few months ago a middle-aged man consulted me because of abdominal symptoms. Typical hunger pain was present and there was an abundance of free hydrochloric acid in the gastric contents. I diagnosed duodenal ulcer. A distinguished surgeon to whom I referred the patient thought it was colitis and sent him to Harrogate, where he was treated without benefit. Three months later a hardness developed in the epigastric region. An exploratory incision showed inoperable carcinoma of the stomach and liver.

During the past 18 months I have had in my wards, first, a case diagnosed as a simple ulcer of the stomach in which there was an excess of free hydrochloric acid in the stomach contents; it was operated upon and found to be cancer. And, secondly, a case which was thought to be cancer of the stomach, in which there was no free hydrochloric acid in the gastric contents; operation in that case showed simple ulceration with considerable inflammatory thickening, which could be felt as a definite hardness in the pit of the epigastrium around the pylorus.

The gastric crises of tabes are occasionally mistaken for stomach ulceration, more especially if, as is sometimes the case, there is hæmatemesis. Since Dr. Hale White directed attention to this point we all, I suppose, recognised that gastric pain, vomiting, and hæmatemesis—in rare cases, even, fatal hæmatemesis—may occur in young women without any obvious ulceration of the stomach. I am disposed to think that in some cases of this kind a superficial abrasion or ulceration was present, and that it healed before the stomach was inspected by the surgeon or pathologist. The occurrence of hæmatemesis in cases of appendicitis may be very misleading. Some years ago I saw a case of acute peritonitis, in which there had been recent hæmatemesis, and diagnosed it as an ulcer of the duodenum which had perforated. Mr. Stiles operated and found that the peritonitis was due to appendicitis. Speaking of appendicitis, I may say that about two years ago I had under my care in hospital a case of pre-ataxic tabes, with very severe intestinal crises, in which an operation for appendicitis had been performed. I was not able to get information as to the condition of the appendix, but I strongly suspect that the symptoms for which the operation was undertaken were due to the tabes, and that the appendix was healthy.

I sometimes think that there is a tendency to attach too much importance to some of the instrumental and other elaborate methods of diagnosis which have recently been introduced—as, for instance, the graphic methods concerned with the heart and circulation—and to underestimate an all-round clinical experience and knowledge. It has recently been suggested that erythema nodosum is a tuberculous condition, one of the grounds for this conclusion being the very marked von Pirquet reaction which occurs in that disease. I admit the fact, but do not agree with the conclusion, for in a condition like erythema nodosum, in which the skin and subcutaneous tissues are more prone to inflame than in health, a positive von Pirquet seems to me to be of little or no importance as a sign of tubercle.

I do not for a moment intend to imply that I undervalue the importance of these instrumental and other methods of clinical investigation. Quite the contrary; the information which they give us is often all-important for diagnosis and in some cases of great value for prognosis and treatment, but they have their place. For the purposes of successful prognosis and treatment nothing will ever replace an all-round knowledge based upon a wide and extensive clinical experience. As an illustration of the value of these instrumental methods, I may mention that I find the sphygmomanometer of great use in demonstrating high blood pressure in cases in which dropsy and other symptoms of cardiac failure are due to, or are associated with, increased peripheral resistance—arteriosclerosis and contracted granular kidney. In these cases, which are often diagnosed as cases of primary mitral regurgitation—a mistake which in my experience is very frequently made in practice—it is sometimes extremely difficult or impossible to detect the high blood pressure by means of the finger.

Mistakes are sometimes due to *too little importance being attached to some fact or facts.* One is apt, for example, to ignore or underestimate the importance of an opinion expressed or hinted at by others, when that opinion does not coincide with one's own view. A case occurred in my practice, now more than twenty years ago, which brought this source of mistakes very forcibly to my mind. In that case, if I had not been able to correct my mistake, very disastrous results would have followed.

ILLUSTRATIVE CASES.

An old gentleman came into my consulting-room with a robust, healthy-looking man, aged 38. He stated that this gentleman was to marry his daughter the following day, but that they had just received a telegram from one of our distant colonies saying the gentleman's relatives objected to the marriage unless I thought it might take place. The prospective bridegroom stated that when he came to this country some eight weeks previously he was run down, that he had quite recovered, and that he now felt perfectly well. The prospective father-in-law stated that neither he nor his family had noticed anything amiss, either physically or mentally, with the supposed patient. With the exception of a little tremor of the tongue, a little thickness of speech when the patient first came into my consulting-room, and some unsteadiness in "fixing," while he was being examined with the ophthalmoscope, I found no evidence of disease, either physical or mental, and stated that I did not feel justified in prohibiting the marriage. On thinking over the case, I became more and more convinced that the bridegroom's relatives would not have telegraphed in the way they had done unless they had good reason for supposing that there was something seriously wrong, and I came to the conclusion that he was probably suffering from general paralysis of the insane, and that it was clearly my duty to stop the marriage. I went early the next day to the prospective father-in-law's house, had another interview with the bridegroom, satisfied myself that the case was one of general paralysis of the insane, and advised that the wedding should be postponed. This was agreed to. Further symptoms soon developed, and before long the patient was sent to an asylum. There were some dramatic features connected with the case, but even at this length of time I do not feel myself at liberty to mention them.

A number of years ago a photograph of a patient in an extreme state of muscular atrophy came under my notice. I ventured to doubt the diagnosis—pseudo-hypertrophic paralysis—and said that it looked much more like a case of poliomyelitis anterior acuta. Some years later I followed up to post-mortem examination a case of pseudo-hypertrophic paralysis which, in its later stages, presented identical appearances with the case I had criticised. A distinguished foreign neuropathologist, on looking through some of my photographs, made the same criticism on my case as I had made on the other case; he was only convinced that it was a case of pseudo-hypertrophic paralysis, and not a case of poliomyelitis anterior acuta, when I

told him that two brothers of the patient had had the disease, and when I showed him sections of muscle which presented all the typical characteristics of pseudo-hypertrophic paralysis.

SUPPOSED MISTAKES OF OTHERS.

Early in my career I learnt *how cautious one should be in publicly criticising the supposed mistakes of others.* In the year 1877 I published a case in which pigmentation of the skin was present during life, and in which (in addition to other lesions) complete caseous destruction of one suprarenal capsule, the other being healthy, was found after death, and suggested that the skin pigmentation was due to the suprarenal lesion. A distinguished assistant physician and lecturer on physiology criticised this conclusion, and stated that Addison's disease was never due to destruction of one suprarenal. Well, I was a young man, more sensitive than I am now, and I felt the public criticism a good deal. But I was able to turn the tables upon my critic, for, on consulting Dr. Greenhow's work, I found that two cases of Addison's disease had been met with in which one suprarenal only was diseased, and that one of these cases had actually been seen and diagnosed as Addison's disease by the very gentleman who had criticised me.

BIASSED JUDGMENT.

Errors in diagnosis are often due to the fact that *one's judgment is warped or biassed* from some cause or another. Most of us probably know how difficult it is to diagnose and treat illness in oneself or in members of one's own family. One's judgment is upset by anxiety and fear; all sorts of terrible possibilities occur to the mind and prevent one taking a cool and level-headed view of the case. We all know how frequently medical students imagine that they are the subjects of heart disease; they come into one's consulting-room depressed and believing they are the subjects of grave organic disease; they leave a few minutes later cheerful and feeling quite well. Probably some of my audience may, because of some temporary fibrillary twitchings, have imagined that they were the subjects of progressive muscular atrophy, or, because of some gouty pains, that they were suffering from tabes.

On the other hand, one occasionally sees the exact reverse of this picture—a medical man the subject of advanced organic disease ignoring it or making light of it, and of the symptoms which it produces, in the most extraordinary way.

Cases of euphoria.—A distinguished member of the profession, in the last stages of cardiac valvular disease with dropsy, at more than one of my visits pointed out with great satisfaction the increased measurement of his calves, thinking, or professing to think, that it was indicative of increased muscular nutrition. A highly intelligent medical man, aged 56, arrived in Edinburgh, invalided home from India, in a dying condition—profoundly cachectic-looking, emaciated to the last degree, so weak that he was unable to walk across the room, with an unhealthy sloughing ulceration of the cornea. He believed that there was nothing of importance the matter, and that the great weakness and extreme emaciation were entirely due to the small doses of morphine which he had been taking. A hard tumour, fully the size of a child's head, evidently malignant, occupied the upper and central parts of the abdominal cavity. The patient and his wife were amazed when this tumour, which could not only be felt with the greatest ease, but which formed a visible projection, was pointed out to them. The patient died a few days after his arrival in Edinburgh.

We all know how *one's judgment is apt to become biassed in favour of some particular theory or idea*, and how, under such circumstances, one sees everything in the light of that idea. Some of the differences of opinion which arise in railway and other compensation cases are due to the fact that the doctors on one side are apt to attach too much, and the doctors on the other side too little, credence to the patient's statements and complaints.

The difficulty of deciding whether a patient is suffering from organic disease or merely from functional disturbance of the nervous system is often very great, even in ordinary private practice, and in cases in which there is no question of compensation—in cases in which there is no suspicion of malingering or of wilful exaggeration. On the one hand, we meet with cases—cases, for instance, of disseminated sclerosis and early general paralysis of the insane—in which grave organic disease of the nervous system is mistaken for hysteria or functional derangement; and, on the other hand, cases in which functional symptoms are thought to be indicative of grave organic disease; in a third group of cases symptoms due to organic disease and functional derangement are both present. Now if those of us who have given special attention to the study of diseases of the nervous system have sometimes difficulty in deciding in which of these groups a case should be placed, it is not to be wondered at that others whose knowledge and experience of nervous disease are, in comparison, very limited, should often have great difficulty in coming to a conclusion, deciding the question, and that differences of opinion, which to the lay mind may seem extraordinary, are apt to occur in courts of law.

All of us who are engaged in hospital practice, and especially those of us who see many nervous cases, will, I am sure, agree that since the passage of the Workmen's Compensation Act, cases in which nervous symptoms are developed after injuries, or supposed injuries, have become much more common; and that in these cases, whether the symptoms are indicative of organic lesion or of functional disturbance, the duration of the illness has become much prolonged. My experience shows that in these cases the patients do not get well, or get well with difficulty, so long as the question of compensation is pending. I personally have little doubt that when the National Insurance Bill is passed the same result will follow in some, perhaps many, of the non-traumatic cases—in cases of ordinary illness—and that the amount of attendance required in the case of patients compulsorily insured will be very much greater than has been calculated. Some people seem to think that it is easy to detect malingering. Those of us who are experienced know that there is nothing more difficult. In the great majority of cases it is not a question of saying whether a patient has disease or has no disease, for, in my experience, actual malingering, when there has been no injury and when there is no disease, is, comparatively speaking, very rare. The difficulty chiefly occurs in cases in which the patient is actually ill or has recently been ill, in saying whether the illness or disease from which he is suffering or has recently suffered will account satisfactorily for all of the symptoms; in saying whether the symptoms which are still present would still have been present provided there was no question of compensation. Conscious or unconscious exaggeration of symptoms, and conscious or unconscious refusal to get well, are, in compensation cases, exceedingly common. It is often extremely difficult, even for the most experienced and expert physician, to give a positive opinion in cases of this kind. It is a practical question, I think, whether such conditions as neurasthenia and hysteria should not be excluded from the medical benefits under the National Insurance Act, though this would, of course, entail hardship on some genuine sufferers.

INADEQUATE OBSERVATIONS.

Erroneous therapeutic conclusions, based on too limited a number of observations, are common; and the worst of it is that these premature conclusions sometimes get into the text-books, and are copied from text-book to text-book, until finally it is definitely stated, and generally accepted, that such and such a drug is of value in such and such a disease. Remarkable coincidences, too, occur which tend to foster the production of errors of this kind. It is a curious fact that the first cases which one treats with a new drug are sometimes the most successful. The first case of pernicious anæmia which I treated with arsenic lived longer (13½ years) than any of the many other cases which I have since treated. That was no doubt a pure coincidence. In the first three cases of psoriasis which I treated with thyroid extract the results were extraordinarily successful. That was perhaps not entirely a coincidence. I have had many other successful cases since, and also many unsuccessful ones. My first cases were all treated with the raw gland, not with tablets, and were all females. I am disposed to think that the raw gland is more efficacious than some tablets, and that psoriasis in the female is more amenable to thyroid treatment than psoriasis in the male. The thyroid gland seems to be more active in the female, and exophthalmic goitre and myxœdema are, as we all know, much more common in the female than in the male.

Nomenclature.—Let me say a word or two regarding nomenclature. Every one will, I suppose, agree that it is a mistake to name a disease after its discoverer. The name should, if possible, give some information as to the nature of the disease or as to its leading clinical characteristics. Is it too much to hope that in the course of time such terms as "Bright's disease," "Graves's disease," "Addison's disease," which are very firmly rooted, will be discontinued? The term "Graves's disease" is specially unfortunate, for in Germany the priority of Graves to the discovery is disputed, and the condition is termed "Basedow's disease." Even at the present day the unfortunate system, as I think it is, of naming diseases after their discoverers is still sometimes followed. A distinguished authority has recently suggested that the term "pernicious anæmia" should be discontinued and the term "Addisonian anæmia" or "Addisonian idiopathic anæmia" given to the disease. Now Dr. Hunter's most important observations and researches show that the disease is probably due to destruction of red blood cells, chiefly in the portal circulation, probably the result of a toxin absorbed from the gastro-intestinal tract. If the term "pernicious anæmia" is to be discarded (but I think this would be a mistake, for I maintain it is a good term which correctly represents the ultimate course of the disease under our present methods of treatment, and correctly differentiates this from other forms of idiopathic anæmia), I would, until the exact cause of the disease is definitely determined, suggest the terms "gastro-intestinal hepatic anæmia" or "gastro-intestinal toxic anæmia" as more suitable than "Addisonian anæmia."

Injurious Effects of Diagnostic Errors.

I have said nothing as to the *injurious effects which may result from diagnostic mistakes and erroneous conclusions.* Most of us probably know to our cost how harmful a mistake in diagnosis—it may be even a quite excusable mistake—may be. On the other hand, many of us have no doubt gained credit and reputation from a correct diagnosis; but while this is so in occasional instances, the public are often quite unable to appreciate at its true value a successful diagnosis in a difficult medical case.

I needly hardly say that the correctness of the diagnosis is often of very great importance to the patient. Take, for example, a case of functional nervous derangement. The prognosis and the success of the treatment entirely depend upon the correctness of the diagnosis. If the case is merely functional, we can, in many cases at all events, cure it, or temporarily cure it, for relapses not infrequently occur; if the case is one of organic disease we are unfortunately in many cases unable to cure it. And here I would point out that it is a mistake to suppose that mere isolation in a nursing home or hospital and a course of so-called Weir-Mitchell treatment will of itself cure the functional cases. In many cases the success of the treatment depends entirely upon the personal influence of the doctor and of the nurse. A doctor who has been treating a case of this kind without success in the patient's house will not be likely to cure her by removing her to a nursing home and putting her through a course of Weir-Mitchell treatment. A doctor who is not sure of his diagnosis, a doctor who cannot impress the patient with confidence and authority, rarely deals successfully with these cases. The composition of the medicine which is prescribed is, in some of these cases, of little or no consequence; distilled water given hypodermically is often very efficacious; the main object of the medicine is to keep up the mental effect produced by the favourable and confident opinion of the physician, and to impress the patient with the belief that something active is being done to cure her. Speaking of distilled water, I may mention an amusing case which occurred in my hospital practice a few years ago. A young woman came home from South Africa because of very severe muscular spasms, which on examination were found to be due to functional disturbance. She was treated by the milk-isolation method, the faradic current, and hypodermic injections of distilled water. In showing the case to my clinic, after her recovery, I emphasised the importance in such cases of the powerful remedy H_2O given hypodermically, and was surprised to see that the patient was very much amused. It appeared that she was a school teacher who was in the habit of giving instruction in elementary chemistry. Fortunately she was cured before she knew the composition of the remedy.

Unfortunate results of a far-reaching kind to the public at large are sometimes due to erroneous conclusions and opinions. Take, for example, the subject of tuberculosis. Koch's conclusions regarding the therapeutic value of tuberculin, Koch's opinion that bovine tuberculosis cannot be communicated to man by milk through the gastro-intestinal tract, were, I think, to say the least of it, unfortunate. The same statement applies, I think, to the late Sir Richard Thorne Thorne's antagonistic views on the compulsory notification of phthisis.

Occasionally, on the other hand, our mistakes lead to beneficial results. In the first case of myxœdema which I treated with thyroid feeding I gave far too large a dose of the raw gland, with the result that acute thyroidism nearly caused the death of the patient. During convalescence the skin peeled off in large flakes; the copious desquamation which resulted from the overdose of the remedy suggested the advisability of employing thyroid extract in the treatment of psoriasis and other forms of skin disease.

I have tried in these, I fear somewhat fragmentary and commonplace, remarks to bring before you some of the chief causes of our diagnostic errors and mistakes, and indirectly to point out that the only way to avoid diagnostic mistakes is, first, to gather carefully and correctly the data—the facts on which the diagnosis has to be based—by exhaustive and accurate clinical observation and examination; secondly, after these data have been obtained to weigh them impartially and judicially, taking all the facts into consideration, avoiding, so far as possible, preconceived opinions, giving due weight to the symptoms and sensations of the patient as well as to the physical signs; and thirdly, to draw a logical and correct conclusion from the premisses. If what I have said will stimulate some of you to observe your cases with greater thoroughness and interest, and will help you to avoid some of the mistakes which I myself have made, I shall be well content.

Address in Surgery

Delivered at the Seventy-ninth Annual Meeting of the British Medical Association

By JORDAN LLOYD, M.D., M.Sc. Birm., F.R.C.S. Eng.,

CO-PROFESSOR OF SURGERY, UNIVERSITY OF BIRMINGHAM; SENIOR SURGEON, QUEEN'S HOSPITAL, BIRMINGHAM.

Mr. President, Ladies, and Gentlemen,—My first desire is to thank—and to earnestly thank—my medical friends for their kindness in suggesting to the Council of the Association that I should be invited to deliver the address in Surgery in my native city. The acceptance of this suggestion by the Council I recognise rather as a mark of its confidence in the arrangements committee than an expression of opinion on my fitness to bear the honours and the burden of so exalted a position. For that mark of confidence I thank the Council, and for the high distinction I have received at their hands I am profoundly grateful.

It is not unfitting at this moment to refer to the recent death of one of the greatest of the older school of Birmingham surgeons. Only a few days ago the last of my surgical teachers passed peacefully away at a ripe old age, and after a long and well-earned retirement from the strenuous labours of a hard professional life. Furneaux Jordan was one of Nature's gifted sons—intellectual, original, honourable, courteous, enthusiastic, and artistic. He was a born teacher and a clever surgeon, and to an early association with him and his work I owe much of whatever surgical success I may have been fortunate enough to attain.

1856. Langston Parker.

In 1856 (the Branch being scarcely two years old) the first annual meeting of the Association in Birmingham was held, and the first Address in Surgery delivered by a Birmingham surgeon—Mr. Langston Parker—the subject of his address being the Treatment of Cancer by Caustics. He advocated the caustic method of treatment in nearly all

forms of cancer on or near the surfaces of the body, either cutaneous or mucous.

The experience of a moderately busy surgical career (says Mr. Parker), during which time the treatment of an unusual number of cancerous diseases has fallen to my lot, painfully impressed me, as it must have done other surgeons similarly placed, with the inutility of operations with the knife performed for the removal of the disease.

Many of the cases described in detail, upon which his opinions were based, are as remarkable as they are interesting, and furnish material over which a thoughtful and unprejudiced person may pause to reflect. The caustic treatment of cancer by these older methods is to-day regarded as almost criminal; its practice is chiefly in the hands of quacks and charlatans. I say "chiefly" for two reasons: there are still a few surgeons—and I confess to being one of them—who occasionally practise this older method in certain superficial cancers where cutting operations are declined, and with very satisfactory results. There is a much larger body of medical practitioners who deem it legitimate to attempt the cure of cancer without operation—superficial as well as deep—by means of more modern inventions, and doubtless with some success; but I have seen their successes and I have seen their failures, and any wonderment I may have experienced from the former has been overwhelmingly dissipated by the tragedies of the latter. A few years' experience in the surgical wards of the workhouse infirmary of a large city teaches you something of the failures of our art in many directions, for there are to be seen the derelicts of surgery, drifting unrecorded and unproclaimed into the silent ocean of eternity.

The name of Langston Parker will always be remembered as one of the earliest of the English scientific writers on syphilis, and the originator of the treatment of this disease by mercurial fumigation.

1872. OLIVER PEMBERTON.

The second annual visit here was in 1872, when my revered old master, Oliver Pemberton, gave the Surgical Address. He was a surgeon of a somewhat similar type to his predecessor—full of the better characteristics of human nature. He was a manly man, genial, kindly, courteous, conscientious, well-informed, of sound judgment and wide practical experience. He was a fine specimen of an old school of surgeons which has almost ceased to exist—the school which gave us in this country Sharp and Cheselden, the Hunters and Coopers, Syme and Fergusson, Brodie and Paget, and a few great masters still with us.

Mr. Pemberton spoke of the great cities of these kingdoms as so many centres of surgical study, having features marked and distinctive, created no less by local than by personal circumstances, and submitted to his audience the fruits of personal observation connected with some of the chief maladies that demanded the skill of the surgeon here in Birmingham at that time—surgical aneurysms, lateral lithotomy, and urethral stricture being the matters of all others which had chiefly engaged his attention during his 30 years' labour as a practising hospital surgeon. Although this address was delivered no longer ago than the days of my own apprenticeship, these chief maladies which then demanded the skill of the surgeon have only a passing interest for him at the present time. Surgical aneurysms are among the rarest of our surgical disorders, and interest us now chiefly by reason of the ingenious but misguided and unnecessary efforts which are made to devise operations for their cure, more complicated, more dangerous, and less trustworthy than the old procedures of Anel, Hunter, and Syme. Lateral lithotomy has fallen into disuse, satisfactory as an operation though it be. Early in my practice I had a run of nearly 60 consecutive cases without a death; and as for urethral strictures, except when they are impermeable or are complicated by urinary extravasation, multiple fistulæ, or the like, their hospital treatment is now left usually in the hands of a house surgeon.

1890. LAWSON TAIT.

At the last annual meeting in this city in 1890 Lawson Tait was on all hands recognised as the most fitting surgeon to deliver the Surgical Address, and spoke from this platform to a large and expectant audience. His discourse, like himself, was broad, vigorous, daring, dogmatic, and delivered with a style and an ease peculiarly his own.

Much of that address of 21 years ago might appropriately be delivered again to-day. The need for stirring change in the modern teaching of anatomy and physiology to students who are to become practitioners of medicine, the advantages of an apprenticeship system, the need for technical instruction in the handicraftmanship of our profession, the changes in surgical methods and the extension of surgical possibilities, the need for more uniform and more exact records of results, and the influence of fashion in surgery and medicine are themes upon which there is still much to be said.

It was here in Birmingham that Tait's great position was made, and within almost a stone's throw of this hall that most of his surgical work was done. He was a remarkable man—perhaps the strongest personality I have known. In some ways he was a giant, and the power of the man held you like a vice. As a surgeon he was a genius; justice has not yet been done to him, and possibly never will be, for the part he took in that wonderful development of abdominal surgery which occurred in the last quarter of the nineteenth century.

After completing his education in Edinburgh, and holding one or more house surgeoncies in provincial towns, Tait bought a general practice in a Birmingham suburb, and there began his life's work. From this modest position, with no hospital appointment at that time, and no great local influence, he set out on a surgical career, and raised himself in a few years—and in spite of intense opposition at home and at a distance—to a position in the surgical world which was unique. Like other great men, he made mistakes, and possessed himself of faiths which had to be abandoned, but the facts remain that he was the first surgeon who attempted to save the life of a human being dying from the internal hæmorrhage of ectopic pregnancy, and he was the first to open the abdomen successfully for the deliberate removal of stones from the gall-bladder. The operative treatment of diseased Fallopian tubes, and of ovaries, for abscess, were extensions of pelvic surgery entirely his own; he was the first to draw distinctions between ovarian and parovarian tumours; he was one of the early pioneers of kidney surgery, and amongst the first to perform laparotomy for acute and chronic peritonitis, and for peritoneal hydatids; he was the first advocate of abdominal section and drainage for suppurating extraperitoneal hæmatoceles. His ingenious method of performing perineorrhaphy, and finally his persistent advocacy of the claims of exploratory operations, establish a record and demand a recognition such as few men have been privileged to merit.

Tait's first operation for gall-stones was successfully performed on a woman, a patient of Dr. Collis of Bridgnorth, in August, 1879, and it is interesting to note that it was carried out by him with "complete antiseptic precautions."

The story of his early experiences in ectopic gestation is as interesting as it is historical, and may best be told in Tait's own words:—

In the summer of 1881 (he says) I was asked by Mr. Hallwright to see with him in consultation a patient who had arrived by train from London in a condition of serious illness, that illness having been diagnosed by Mr. Hallwright as probably a hæmorrhage into the peritoneal cavity from a ruptured tubal pregnancy. The patient was blanched and collapsed. The uterus was fixed by a doughy mass in the pelvis; there was a considerable amount of effusion in the peritoneum, but no distinct tumour could be felt above. I agreed with Mr. Hallwright as to the nature of the lesion. This gentleman made the bold suggestion that I should open the abdomen and remove the tube. The suggestion staggered me, and I am ashamed to have to say I did not receive it favourably. I saw the patient again in consultation with Mr. Hallwright and Dr. James Johnson, and again I declined to act upon Mr. Hallwright's request, and further hæmorrhage killed the patient. A post-mortem examination revealed the perfect accuracy of the diagnosis. I carefully injected the specimen, which was removed, and found that if I had tied the broad ligament and removed the ruptured tube I should have completely arrested the hæmorrhage, and I now believe that had I done this the patient's life would have been saved.

The man who put on permanent record such a story of a professional brother and himself was no ordinary person. It was not until Jan. 17th, 1883, more than two years after the incident above related, that his first operation was undertaken. The woman—a patient of Dr. Spackman of Wolverhampton—died immediately after the operation was finished. The reason of her dying Tait at once had the strength to recognise and the courage to confess. He says: "It was due to my own 'bungling.'" The partially extruded tubally attached placenta had obtained new attachments to neighbouring coils and intestines, the most cautious separation of which occasioned fast and copious bleeding at every

point. The lessons he learnt from this first case were priceless. He saw that placental attachments must be left severely alone, that nothing more was required than the removal of the bleeding tube and the clearing away of the escaped blood, and that rapidity of execution was an essential factor in securing operative success. His first successful operation was performed on March 3rd, 1883, on a patient of Dr. Page of Solihull, and during the next five years he operated 41 times with one death.

We can forget Tait's errors in the greatness of his achievements. His operation for the removal of the appendages for the treatment of bleeding uterine myoma has not fulfilled the faith he had in, nor justified the claims he made for, his discovery. Next to ectopic pregnancy it was the subject which most interested him, and the operation he originated for its treatment was the piece of his life's work of which he was most proud. Writing of this operation in 1889 he said:—

> The permanent and complete efficacy of this method of treatment has been established by evidence beyond all cavil; in fact, it stands unrivalled in the history of modern surgery; we have an absolute cure in our hands. I am satisfied the risk to life may be reduced to a vanishing point.
> Hysterectomy (he goes on) is a coarse and much more dangerous method of accomplishing the same ideal (arrest of menstruation), and it is an operation I detest.

Tait was wrong; for few surgeons, I imagine, follow this practice now, although some among us occasionally had—I certainly did—the satisfactory results claimed by him for the procedure. Hysterectomy is the treatment generally adopted to-day for all uterine myomata, whether bleeding or not. I question whether the last word has yet been said on the necessity for the treatment of this class of non-malignant uterine tumours by the major sacrifice of a very useful organ.

In the eyes of his contemporaries Tait's greatest error—indeed, it was looked upon as his besetting sin, which nothing could condone—was the attitude he took up with regard to early Listerian practice and teaching. Whilst accepting to the full the Pasteurian theories of fermentation and putrefaction, he denied that they applied alike to *living* as to dead tissues. He held the view—in common with other distinguished men of his day, and with a still greater number at the present time—that *living* tissues are themselves capable of dealing with the germ life of the ordinary atmosphere, and on the strength of this faith he was then removing ovarian tumours, and without the aid of the Listerian methods of his time, with a mortality of between 3 and 4 per cent. His wounds were dressed with dry absorbent cotton, very much as used everywhere to-day, as Gamgee had employed for years previously, and as I have done since I was Gamgee's house surgeon in 1877.

I should like to say a few words here on what is now euphuistically spoken of as "surgical technique," formerly as wound treatment, particularly with regard to its ritual and its expense. The great principles upon which operative success depends are to-day exactly the same as when Lister first preached the gospel of antisepsis. Absolute cleanliness is the essence of the measures by which he carried those principles into practice. Many as have been the modifications of our operative methods since the early "seventies" of last century, it is upon the completeness with which this central idea has been secured that the success of each method depends. It needs but little ceremonial to make and keep us clean either in body or in spirit. Simplicity, sincerity, and steadfastness will suffice in both. The modern tendency to make of a surgical operation a kind of ritualistic function is greatly to be deplored. Harm often results therefrom I am sure. We can be careful without being fastidious, and efficient without becoming hysterical, and elaboration of ceremonial will not condone a want of manipulative dexterity or absence of readiness in emergency.

Soap and scalding water are our safest and simplest antiseptics, and if we add spirit to the list, the scruples of the most sensitive of surgeons should be satisfied. Linen straight from the laundry costs but little, and is all-sufficient. Gauze can be purchased for less than a penny a yard, silk for 3*d.* a skein, clean cotton-wool for less than a shilling a pound, and bandages for a few coppers each. All these are inexpensive, but all are efficient, and all are simple. The increasing cost of surgical work is chiefly due to the caprices of fashion and the demands of ritual, and partly also to the fancies of architects and the seductive enterprise of surgical instrument-makers. Good surgical work can be done in a clean and well-lighted, airy bedroom if the surgeon will only take the necessary trouble. Many of the improvements of a modern hospital are as much for the convenience of the working staff as for the welfare of the patients.

EXPLORATORY OPERATION.

Exploratory operation as a means of accurate and early diagnosis had been advocated long prior to the days of Tait, but he it was who especially extended the application of this great surgical principle to diseases within the abdominal and pelvic cavities.

In 1876 "the great impediment to the adoption of gastrotomy (abdominal section) is the uncertainty of diagnosis," wrote Parry of Philadelphia, and Tait commenting on this statement in 1889, said:

> Mark the importance of this sentence, for this sentence it is, reiterated by almost every writer on abdominal surgery up to 1878, and continued as a tendency by a great many still, which has stood in the way of our success. I have long since thrown it to the winds, and when I find my patient *in danger of death* from conditions within the abdomen which do not seem to be clearly of a malignant nature, but a correct diagnosis of which is impossible, I open the abdomen, and at once make the diagnosis certain, and a successful treatment possible. I do the same thing also when the conditions are such that the patient's life is miserable by reason of suffering which cannot be relieved, or, at least, has not been by all other measures.

The result has been an enormous advance in abdominal surgery, obtained only after a severe struggle with the authority of the elders, who asserted that the abdomen was a region into which the writs of ordinary surgical laws should not run. He further adds, and with characteristic brusqueness:—

> Absolute accuracy of diagnosis in the abdomen is *very far* from being possible: only the ignorant assert that it is, and only fools wait for it.

The wider acceptance of this great principle of exploration has done more to further the advance of surgical knowledge than anything since the introduction of antiseptic surgery. The general body of the profession takes somewhat exaggerated views of its risks and its disappointments, confiding more in new discoveries of a non-operative kind—imaginary or real, orthodox or unorthodox, scientific or empiric—frequently confusing exploration with experiment, and not altogether without reason. The two measures are essentially different; one is a matter of diagnosis, the other of treatment; one is often a sacred duty, the other is sometimes a surgical sin; and whilst I plead for a more generous consideration of the advantages of the former, I urge a strengthened watchfulness of resistance to the latter. To uncover a kidney to determine the presence or absence of a stone therein is an exploration; to stitch the dropping organ to the ribs because a head aches is an experiment. Experimental operations to-day are greatly on the increase, and are not to be justified merely for the reason that if something is known to be the matter, something must be done; or that they can be carried out with little danger to life; or that the malady for the relief of which the experiment is made is positively fatal unless something can be found for its relief. Gentlemen, there are many things in the world we cannot change, and to attempt to alter them is an act of folly. Water will continue to run downhill, however desirable in human interests it might be at times that it should flow in the opposite direction. We cannot attain the unattainable in surgery more than in other things. We must accept the inevitable, however sadly, or however great the cost.

I do not say that experiment shall not enter into the question of operations at all; it would be illogical were I to go so far, for the reason that much of the work of the daily practice of every medical man is essentially of the nature of experiment, and it is often only through experiment that later efforts come to be made in the right direction.

In a mere exploratory incision for the purpose of ascertaining whether an abdominal tumour is malignant or not no special difficulty is experienced or risk incurred, an incision large enough to admit a finger being all that is necessary. This sort of exploratory operation is practically nothing more than a tapping, but is of the greatest possible value in many circumstances. The whole abdominal cavity cannot, of course, be explored through one such incision, and in practice it is rarely necessary that it should be; the surgeon knows beforehand, from objective symptoms, the quarter in which

any malady is situate, and there his exploratory opening will be made. It is surprising what can be learnt by a trained and educated finger passed through the abdominal wall at certain sites.

If a complete abdominal exploration has to be made through a single incision the opening must be made sufficiently large to admit the whole hand, and is, of course, more serious, but even then the death-roll is a negligible quantity, providing the exploration is carefully and rapidly made and nothing beyond this is done. This larger incision is often necessary, to determine whether a particular tumour can or cannot be removed. In this exploratory handling of malignant tumours it is of vast importance that the capsule of the tumour be not injured, owing to the great vascularity of the tissue contained within, and the difficulty experienced in checking such bleeding. Did time allow I could relate many instances where the neglect of this elementary rule has led to disaster of the most distressing character in what ought to have been simple and safe procedures.

KIDNEY DISEASES AMENABLE TO SURGICAL TREATMENT.

Great as has been the advance in our means and methods of investigating the nature of surgical kidney diseases during the last few years, certainty of diagnosis is still far from general, and exploration as the final method of determining the exact nature of a renal malady is still sometimes necessary, and may always be so in such affections as hypernephroma, adenoma, papilloma of the renal pelvis, or congenital cystic disease.

In my student days kidney disorders were dealt with solely by the physicians, whose time and interests were chiefly concerned with Bright's disease in one or other of its forms. I remember quite well how my professor of medicine, at the end of a series of lectures on Bright's disease, disposed of all the other kidney troubles within a couple of hours. Since those easier days "surgical diseases of the kidney" have whole volumes to themselves, and their curability or relief is more in our hands than was formerly thought to be possible.

The great bulk of these diseases are to be diagnosed by simple methods, by urinary investigation, by physical examination, by accurate history, and finally by clinical common sense. It is only in exceptional cases that the cystoscope, the radiograph, and the ureteral catheter are wanted, and sometimes they may be wanted badly. An otherwise healthy man subject to acute, paroxysmal, unilateral lumbar pain, shooting forward to the groin and testicle, aggravated by exertion, with concurrent or consecutive hæmaturia and oxaluria, ought to have a renal calculus; and whether your cystoscope, or ureteral catheter, or radiograph tell you so or not, should his attacks continue to recur an exploratory operation of the painful kidney ought to be made.

There is a feeling in the minds of most people that instruments of precision, such as the Roentgen ray apparatus, the camera, the 'graphs and 'scopes of various kinds cannot possibly err, that their evidence is absolutely unimpeachable. This may be true of the instruments themselves, but whenever and wherever human judgment or observation has to come in, there also comes in liability to error. Let me illustrate my meaning by a few personal experiences of radiography in the diagnosis of urinary stone.

A few weeks ago I operated on a patient from whose right kidney a stone had been removed some 18 months previously by another surgeon, a urine-leaking sinus resulting. An expert radiographer had recently declared the presence of another stone to which the persisting sinus was naturally attributed. I cut into this kidney for the purpose of removing this stone, which I failed to find. I then removed the kidney with its pelvis and the upper part of the ureter entire. There was no stone anywhere.

More than two years ago I saw a strong, healthy man with classical symptoms of renal calculus. To confirm the diagnosis the radiographer was appealed to. He found no stone in the kidney, but reported the presence of two small calculi in the ureter. Operation was deferred in the hope that these small stones might be passed naturally. After waiting a year I determined to explore both the kidney and the ureter and had a radiograph taken the day before the operation to be sure the ureteral stones had not in the meantime shifted their position. The radiographer then reported that there were two stones in the kidney, each of the size of a horse bean and alike in shape, and that the supposed ureteral calculi were probably phleboliths. I cut on to the kidney from the loin and readily removed one stone, but the second was nowhere to be found. I felt confidence in the thoroughness of my kidney exploration, gave the opinion that the two shadows shown on the plate were shadows of the same object, and closed the wound. The man recovered easily after the operation and has had absolutely no symptoms since.

A distinguished surgeon related to me an exactly similar experience which befell him a year or two ago—where he was led by the dogmatism of the radiographer to reopen a closed wound for a second stone which was not there, and nearly lost his patient in consequence.

A colleague had recently a consecutive series of five cases of ureteral calculus where radiographic evidence was negative; operation proved the presence of stone in every instance.

It is well known that pure uric acid stones may be invisible to radiography, and overlooked renal and ureteral calculi might be assumed to be of this nature, but recent researches of great value carried out in the Liverpool Medical School show that every one of a consecutive series of 24 stones removed by operation and submitted to careful chemical analysis were chiefly composed of oxalates and phosphates of lime. Lime-containing calculi give radiographic shadows, and most, if not all, of the Liverpool cases had been accurately diagnosed and localised before operation.

I have no desire to minimise the value of radiography in the diagnosis of urinary calculus disease; indeed, I recognise it as of the greatest value and feel more at ease in a contemplated nephrolithotomy when I am supported by the confirmatory assurance of the shadow in a radiograph. Its affirmative value is of the high st, but too much importance must not be attached to its negative opinion.

Ureteral catheterisation has its limitations and its fallacies. It is of the greatest use in the detection of albumin, tube casts, and micro-organisms in the urine, from one kidney alone. Obstruction in the ureter cannot be recognised with any degree of certainty by catheterisation; many cases are already recorded where operation has shown that such catheter findings have not existed. Stones in the ureter (as in the urethra) have often been passed over by the catheter without recognition.

A very fair idea of the size and quality of a kidney and of its pelvis can be obtained by a finger inserted through a small exploratory opening in the linea semilunaris; but if a more thorough examination is needed a lumbar incision should be made. A vertical incision from the tip of the last rib downwards gives the best access, but if the ureter is to be followed into the pelvis the oblique downward and forward incision is better. For exploration a kidney should be thoroughly freed from its surrounding tissue and brought on to the loin whenever possible. Stones, tumours, cysts, abscesses, tubercle can be recognised without splitting the kidney by manipulation between a finger in the hilum and a thumb outside.

At the beginning of my professional life stone in the bladder was quite common in this district. Fifteen years later bladder stones were fewer, but kidney stones had more than taken their place; to-day bladder stones are fewer still, kidney stones are not so plentiful, and ureter stones are increasingly in evidence. It is not easy altogether to say why.

APPENDICITIS.

It needs courage nowadays to say anything at a meeting of medical men on the subject of appendicitis, particularly so in the middle of a hot July day. So much has been said and written, and presumably so much has been learned, that nothing now remains to talk about. And yet, strange though it may seem, there are schools of opinion divided on almost every point of the subject on which it is possible for human minds to disagree. The more I see of the disease the more satisfied I am that it is primarily a mechanical affection; that obstruction is an essential factor in its genesis, the consequence of such obstruction being determined and controlled by germ activities on the one hand, and tissue proclivities on the other; that so long as no obstruction exists in the channel of the organ or in its opening into the cæcum the omnipotent germs of the intestinal canal are powerless for evil.

The appendix is part and parcel of the large intestine, fulfilling the same function, receiving the same contents,

altering them in the same manner, subject to the same disturbances and disorders, differing only in the mechanical consequences of its peculiar anatomical construction. The earlier pain of appendicitis is due to tension within the cavity of the organ; the later to the inflammatory involvement of peritoneum. I have seen acute appendicitis in the first year of life; I have seen a first attack come on at 84. The diagnosis of both acute and chronic appendicitis, although often a simple matter, is not always possible without the aid of exploratory incision. It would be better for the public and ourselves if this fact were more constantly kept in mind. It might tend to clear away many difficulties and much misapprehension which arise from time to time between our patients and ourselves where operative measures have to be discussed and operative results explained. Appendicitis is still occasionally wrongly diagnosed, but whereas formerly the disease was overlooked, to-day it is recognised where it does not exist, and when we remember its frequency of occurrence and its gravity, it is not surprising that it is "appendicitis" which usually comes first to mind in an acute abdominal outbreak, occurring unexpectedly during ordinary health.

As a rule appendicitis declares its own presence if we will but listen carefully to the story it has to tell us, but we must listen with an open mind, for it is our preconceived ideas which lead us into error in most of our wrong judgments in all matters. The most reliable and most consistent of its early signs is local tenderness, always to be elicited if carefully examined for in the groin, the loin, the right side of the abdomen, or the rectum. This tenderness signal symptom must be sought for early; it becomes masked and modified by extra-appendical inflammatory extensions. The presence of a localised, well-defined swelling means suppuration either within or outside the organ, and the sooner such swellings are explored the safer for the patient, provided too much is not done at the time. Such localised swellings may disappear slowly by pus absorption and tissue resolution, or more quickly by pus finding its way into an adjacent coil of bowel, usually the cæcum. I need scarcely say that pus appears in the stools only when an abscess has opened directly into the rectum or sigmoid flexure. Localised swelling is absent altogether only in the fulminating general peritonitic type, which is usually fatal whatever may be done for it. If every case of appendicitis was recognised and operated on within 12 hours of inception it would almost cease to be a mortal disorder, and if during the next 12 hours even the general mortality would be lower than it is. After 24 hours consideration has to be given to several matters before one can determine in any given case what is the safest step to be immediately taken, but on one point I am quite satisfied—that any interruption in the forward progress of an improving case calls for immediate operation. Whether it is safer to open the belly before opening the bowels in acute appendicitis or *vice versâ* I cannot discuss to-day. I have tried both procedures, and give my verdict unhesitatingly in favour of the latter. On the wisdom of the interval operation we are doubtless all agreed.

According to the Registrar-General's returns 2,276 persons died from appendicitis during the year 1909 in England and Wales, in the proportion of four males to three females. In the two larger Birmingham hospitals last year 432 operations for appendicitis were performed, and with a mortality of 8 per cent. in the acute cases only. Assuming the disease to be equally prevalent through the whole community—and there is no reason why it should not be—there must be nearly 40,000 cases annually in the United Kingdom, and yet at the time of the last annual meeting of the Association here appendicitis was an unrecorded malady in our hospital statistics, and did not appear in the Registrar-General's returns.

SURGERY OF THE STOMACH.

Abdominal operations have taught us many strange things since the Association was last here concerning the workings of our internal machinery, but none more striking nor more valuable, in my opinion, than the lessons to be learnt from the phenomena attending a successful gastro-enterostomy for pyloric stenosis. Here, prior to operation, we have faulty digestive processes of every conceivable kind flagrantly evident—changes in the acid content, in the peptic factor, in the motor mechanism; with flesh loss, weakening of body and of mind. Every attempt to change this state of things by drugs and diet has failed during a long period of trial. A free opening is now made between the stomach cavity and the gut beyond the site of obstruction—nothing more—no drugs are given, no artificial ferments supplied, no changes in the foodstuffs poured in from above, no electricity, no hypothetical science of any kind, and what do we see? In most cases, at once a remarkable change; every sign of faulty digestion begins to disappear, and in a short time the whole complicated and elaborate process is carried on in a normal manner. It looks, therefore, as if a chief factor in faulty digestion may be undue retention of food in the cavity of the stomach, and that unsuitability of material put into the gastric beaker or abnormal quantities and qualities of the digestive juices added thereto by the secreting glands may be altogether of secondary importance.

I know of no more striking example of surgical advance than is seen in the modern operative treatment of gastric disease, and when we remember how small is the ordinary death-rate of stomach affections this development becomes the more remarkable and can only be explained by an increasing confidence of the profession and the public in surgical operative procedure. Of all the organs of the body the stomach is most subject to disturbance of one kind or another. Dyspepsia figures largely wherever medicine may be practised. Until quite recent times faulty digestions have been dealt with chiefly as purely functional affections. Organic lesions were looked upon as exceptional—the acute ulcer of young women, the atony of middle life, the cancer of the aged, with an occasional pyloric stricture, covered the whole ground of organic stomach disease. To-day the fact is established beyond question that all, or nearly all, chronic indigestion is due to organic gastric or duodenal disease. Although stomach surgery was being performed more than 20 years ago, it is only within the last few years it has made its real advances and established itself on a firm and permanent footing. I sometimes think it is going along too fast, for it is now quite an ordinary thing for a hospital out-patient to reply in answer to your inquiry of "Well, what is the matter with you?"—"I have got indigestion, and want to be operated on"; just as formerly he would have said, "I have got the wind and want something for it."

Accurate diagnosis of stomach disease is not always possible, despite the splendid work already done by the physician, the physiologist, the pathologist, the bio-chemist, and the radiographer. Appeal must often be made to exploratory operation, for it is only by sight and direct touch that precision of diagnosis in stomach diseases can be secured, and it is not until certainty in this direction has been established that the necessary treatment can be determined. Exploration should be the first step in every stomach operation, and one would think it unnecessary to add that unless something definite is found nothing definite should be done; the operator's hand must be restrained unless it is manifestly clear that the structural condition before him demands mechanical rearrangement or removal. There should be no mistakes in the way of speculative operations, even although the opportunity for experiment is before you; the temptation to do something must be resisted.

A considerable experience in stomach surgery, begun more than 20 years ago and continued on up-to-date lines to the present time, leads me to the following conclusions:—That precision in the diagnosis of many stomach diseases can be secured only by exploratory incision, and that earlier resort to this procedure in many cases is very desirable. That where pyloric obstruction is present, as evidenced by periodic vomiting, treatment by posterior gastrostomy is eminently and uniformly satisfactory. Pain in such cases may be altogether absent. That where vomiting is absent or only occasional, and pain is the symptom for which a patient seeks relief, gastro-enterostomy has its failures. That acute ulcers of the stomach, except when perforating, do not demand surgical treatment; chronic ulcers, on the other hand, do; but what that treatment is to be I am uncertain. Some should be excised, some are cured by gastro-enterostomy, some should be infolded, and possibly some should be left alone by the surgeon. That operations for gastric carcinoma are at the present time unsatisfactory, probably owing to their non-early recognition. That dilated stomachs, in the absence of associated lesions such as pyloric narrowing or ulceration, may be left unoperated on. That gastric hæmorrhages are not to be dealt with satisfactorily by surgical operation. They do better in the hands

of the physician. Duodenal hæmorrhages, too, are not readily amenable to surgical treatment. Gastro-enterostomy does not meet their urgent indications, although it may contribute to the healing of the ulcers in which the bleeding originates. That chronic duodenal ulcer is a pathological fact; it is no mere surgical apparition as is sometimes suggested. Its frequency in adult males is remarkable; its diagnosis prior to exploration is highly probable, but by no means sure; its recognition at the time of operation is certain, and its relief by operation is most satisfactory, I cannot say invariably successful. That cancer of the stomach here in Birmingham does not appear so often as a sequel of chronic ulceration as it is said to do in many other places. The majority of patients with cancer of the stomach give no account whatever of long-standing or of past indigestions. It appears usually as a primary indigestion in the middle-aged or elderly, and in all such cases I agree with a recent writer in the *British Medical Journal* that by the failure of medical treatment quickly to relieve such indigestion a suspicion of cancer should be aroused and an exploratory operation at once performed.

INTRACRANIAL AND INTRATHORACIC SURGERY.

Exploration has been of the greatest value in the treatment of intracranial conditions, and has brought into the range of curability many otherwise fatal affections. The purely experimental work of the scientific physiologists has taught us much in connexion with intracranial disorder, but exploratory operation has amended and amplified the knowledge thus acquired, and has made it of practical value in the treatment of disease. Intrathoracic maladies do not lend themselves readily to operative exploration, owing, of course, to the serious disturbance of the respiratory dynamics attending open incisions into the thoracic cavity, but even here its use is considerable.

My own interest in exploratory operation would lead me to dwell longer on this theme, but I must refrain, and devote the time that remains to the consideration of other matters.

INGUINAL COLOSTOMY.

Remarkable are the lessons to be learnt from a consideration of the modern operation of inguinal colostomy in two stages. Stage number one, as you are aware, consists in bringing out of the abdomen through a small incision in its walls a complete coil of the sigmoid flexure, some 6 or 8 inches of bowel, and of fixing the coil outside by means of a glass rod pushed through its mesentery, or in some other manner. A covering dressing of gauze or cotton is fixed over the extruded gut and the patient returned to bed. A mechanical obstruction of the bowels has thus been artificially produced of the most complete kind—I say obstruction as distinct from strangulation. Not the slightest pain follows the procedure; the patient lies perfectly comfortable for many days without a symptom of abdominal disturbance of any kind; nothing is passed per anum; he takes a simple liquid diet and sleeps soundly; he has neither pain nor vomiting; his tongue does not fur and his head does not ache; his pulse-rate is normal and his temperature does not move; his belly is neither distended, tender, nor rigid, and yet during the whole time the obstruction of the bowel continues. To me the object-lesson is of extraordinary interest, and I am constrained to ask myself whether some of the views commonly held and acted upon in connexion with "stoppage of the bowels" may not possibly need revision. I am often called in consultation to see cases of supposed primary "intestinal obstruction," where the symptoms of sudden severe pain, vomiting, and constipation are attributed solely to the fact that the bowels have not been moved for 24 hours or so. Simple arrest in the onward movement of bowel contents clearly does not give rise to these symptoms; some other factor must always be present to produce them, and upon this factor does the obstruction depend. The more I see of acute abdominal disease, the less often do I meet with intestinal obstruction as a primary affection; it is secondary or symptomatic in the large majority of cases. Early in my surgical career I was frequently seeing cases of acute intestinal obstruction, and opened the abdomen for their relief as a routine procedure, invariably finding, as I believed, loops and kinks and twists and indeterminate bands, when something else more real was not in evidence. I published a paper in the *British Medical Journal* at that time, with an account of some 20 operations. Although of late years I have seen much more acute abdominal illness than I did then, I am not meeting one-fourth as many cases of intestinal obstruction calling for immediate treatment by surgical operation. Whether it is that the malady has become less frequent or that the bowels have acquired the knack of unravelling themselves in this age of higher education, or that I am now failing to recognise the malady, or that greater experience has modified my earlier predilections, I leave you to think.

The second stage of this same operation (inguinal colostomy) furnishes further food for reflection on some of the problems of intestinal function and disorder. Four or five days after the first stage has been carried out the coil of gut is exposed—it is lymph-covered and tightly adherent to everything about it; to a certain degree it is inflamed, but it is absolutely insensitive to pain. It may be cut across with scissors, it may be pinched or crushed, it may be slowly burned completely away with the actual cautery without the conscious patient showing the least discomfort at what is being done. The insensitive bowel wall is not dead; it bleeds freely when cut—indeed, its vascularity is excessive, and its sensibility, therefore, if it had any, should be exalted. This absolute insensibility, pervading as it were all the bowel tissues—mucous, submucous, muscular, peritoneal, nervous, vascular, and lymphatic—is hard to reconcile with the common clinical experiences of belly-aches met with daily by every medical practitioner.

INGUINAL CÆCOSTOMY.

It is well known that lengths of the digestive tract, varying from inches to several feet, may be removed without permanently affecting the general health. Whatever may be our final conclusions as to the advantages or the necessity in chronic constipation and in tuberculous joint diseases for doing away altogether with the function of all but the terminal few inches of the large intestine, the fact will remain that such a physiological deprivation is compatible with long and healthful life. More than twenty years ago there came into my hands a woman with a rare form of colon disease, probably inflammatory in its nature, certainly not malignant. She had suffered from bowel symptoms, pain, looseness, irregularity, and slimy stools for the previous 11 years, dating her trouble back to a confinement at that time. She was a confirmed invalid when I first saw her. The rectum was almost occluded; the stools dribbled from her in liquid form, and her distress was very great. On opening the abdomen with the intention of doing an inguinal colotomy I found the whole length of the large intestine from cæcum to anus was indurated, puckered, and contracted to the thickness of a finger, looped like a fleshy rope across the abdominal cavity. Its lumen was narrowed throughout its whole length; it had become practically nothing more than a long fistulous track, with one end at the ileo-cæcal valve, and the other in the perineum. The small intestine was normal in appearance but distended. There was nothing to be done obviously but to make an artificial and permanent opening in the cæcum as near the valve as possible. Cæcostomy is, as a rule, one of the most disappointing and distressing of all operations for the relief of intestinal obstruction. The constant escape of liquid contents from the small intestine directly through on to the skin gives rise to a widespread area of cutaneous irritation and rawness, for the relief of which local treatment is of little avail. The outlook, therefore, for this poor woman was gloomy. She began, however, to improve in health at once after the operation. Little by little she learnt to manage her disablement with greater and greater comfort to herself, and at the end of a year her general health was completely restored. She has lived an active life ever since, managing her domestic affairs, bringing up a large family, and taking an active part in her husband's business. For more than 20 years she has continued in good health, although not a particle of her foodstuff has passed into her large intestine.

RADICAL CURE OF HERNIA.

Operation for the radical cure of hernia is a practical achievement of recent years. The only radical feature in the operations of our forefathers is that they are all radically bad. In 1890 no such operation appeared in the General or Queen's Hospital statistics; last year 476 are recorded. A few hernias were "radically cured" in my student days by the

puzzling operations of Wood and Wurtzel, but the hernias invariably recurred in those patients who were fortunate enough to survive the operations.

There is no one operation practised for each of the several kinds of hernia. Every surgeon has his own methods, and thinks them better than anybody else's, and it is quite possible they may be, but certain definite principles are now established, and so long as they are acted upon, it matters little by what means, results will be almost uniformly good. Recurrence liability varies under many circumstances—age, variety of hernia, fatness, &c.—but, including favourable and unfavourable cases alike, it should be less than 5 per cent. In children and young adults there should be none. The mortality-rate, too, varies in groups of cases, but should aggregate less than ½ per cent. Hernias of all sizes, at all ages, and in all situations, can be satisfactorily and comparatively safely dealt with. The most important step of the operation has to do with the sac of the hernia. The neck of the sac should not be ligatured, but the peritoneum beyond the neck, and when this has been done and cut across below the ligature it matters little whether the sac is removed or not. The closure of rings and canals is said to be a matter of secondary importance; in my opinion it should always be done, except in the inguinal hernias of very young children, and well done too. It is interesting to note that modern operations show the sacs of most hernias to be congenital and not acquired, an anatomical fact observed and insisted on by the anatomist Roser more than 70 years ago, and denied by almost everybody else up to quite recent times. The golden rule in surgery applies particularly to radical cure operations: Know what you want to do; see what you are doing; and do it simply.

PROSTATECTOMY.

Amongst the surgical advances of this present century the treatment of enlarged prostate by enucleation stands conspicuously prominent, and without discussing for a moment the question as to whom belongs the credit of first removing this organ by operation, the credit for having established the faith of the profession in the feasibility of the procedure is undoubtedly Freyer's, the great merit of whose work is in no way affected by small details as to the exact nature of the parts removed, or in the precise method by which their removal is effected. The term "prostatic hypertrophy" is a misnomer, the enlargement being due to the adventitious presence within the substance of the prostate of distinct neoplastic structures, adenomatous in their nature, developed doubtless from the normal gland tissue, but as distinct from simple hypertrophy as the common adenoma of the female breast is from general mammary overgrowth. The reason for the development of these adenomatous masses we do not know; none of the many explanations offered quite fit the facts, but that they are of very common occurrence is certain. As visiting surgeon to the Birmingham Workhouse Infirmary I have access to an enormous mass of pathological material, which ought to be put to better purpose, and ought to be accessible to the students of our medical school. Some years ago I removed post mortem, and carefully examined, the prostates from a consecutive series of 30 men between the ages of 21 and 94, dying from various maladies. Three of the 30 were under 40 years of age, and all their prostates were normal; but of the remaining 27, 5 only were normal, 22 showing well-marked adenomatous growths. The detailed figures are interesting: Of 6 in the forties, 5 were enlarged; of 3 in the fifties, 2; of 8 in the sixties, 6; of 8 in the seventies, 7; 1 in the eighties and 1 in the nineties were both enlarged. Of normal prostates there were 1 in 6 in the forties; 1 in 3 in the fifties; 2 in 8 in the sixties; 1 in 8 in the seventies, and none above that age—that is to say, over 40 years of age less than 1 prostate in 5 was normal, and over 50 years less than 1 in 4.

A discovery such as this was not comforting to a man who was then far advanced in the forties, but all anxiety was quickly allayed by the results of investigation in another direction. At that time there were 1071 men over 50 years of age in the workhouse and its infirmary, at least 750 of whom we may take it had some amount of prostatic enlargement; four only were under treatment for prostatic troubles—a little more than ½ per cent. I quite realise that what is true of a body of men living simple, healthful lives under institutional discipline may not be true of men at liberty to live and to act as they choose, but it is clearly not necessary to advise every man whose prostate is enlarging to submit at once to a radical operation for its removal, not even when early symptoms have begun. I have seen several prostatics living healthy, active lives the whole of whose urine has been drawn by self-catheterisation for 20 years or more without trouble or inconvenience. Prostatic retention occurs sometimes where overgrowth is not present, the obstruction being caused by a true stenosis of the prostatic vesical inlet. The symptoms of this form of prostatic difficulty are like those of ordinary enlargement, but digital examination per rectum discloses a small prostate where a large one might have been expected.

I am performing regularly both suprapubic and perineal prostatectomy, and find that each has its merits, and that neither can claim to be the better for all cases. The suprapubic enucleation of a large soft adenomatous prostate from a man of moderate size is an ideal manipulative procedure—I know nothing more satisfactory in the whole field of operative work; but the enucleation of a slightly enlarged, tough, fixed organ from within the bladder of a bulky drayman is quite another business, and may be more easily and more satisfactorily accomplished by the perineal route. Each operation has its difficulties and its dangers, and in these matters there is little to choose between them. The suprapubic operative mortality is rather the higher in my hands, probably because the more serious cases have been dealt with by this method. The after-results of both operations are about the same. It is impossible to express in figures the functional results of surgical procedures, and one is constrained, therefore, to state them in general terms. Usually the results of prostatectomy are excellent; in the majority functional restoration is complete, and the patient is eminently satisfied; in a fair number, however, marked improvement is all that can be claimed, whilst in a few disappointment follows. Impotence probably always results, but the sexual function is not always abolished. Prostatectomy for carcinoma and tubercle has been disappointing in my hands.

THE GROWTH OF MEDICAL LITERATURE.

One of the trials of a conscientious doctor's life is the flood of journals and new books which constantly overwhelms him. Every one feels the desire to read regularly at least one of the two leading weekly medical journals of his own country—and there ought to be no difficulty in his doing so; but when we find that our own *Journal*, with its Supplement and Epitome, contained last year more than 4750 pages (exclusive of advertisements, of course), more than 13 reading pages for every day in the year, one sees how difficult it is; and when the second weekly is to be read, when the quarterlies, when the new books, when the research, and when the reflection, I do not know. No wonder there are doctors who make no attempt to keep abreast of the times by reading current literature, but are content to treat their patients by methods learnt from their early teachers, and proved to be the best by their own experience, relying on help from a professional brother in exceptional circumstances.

During the last century the memoirs and original works in medicine and the allied sciences numbered at least half a million, and it is not therefore surprising that the great Velpeau said towards the end of his busy days that "the greater part of his life had been taken up in unlearning what was untrue." The man who proclaims a new discovery in a method of treatment or a means of more certain diagnosis incurs a great moral obligation, and the journal which distributes the information to the profession and to the public a greater. It would be better for all of us, doctors and patients alike, if every new discovery could be investigated and approved by an official and competent body of men especially appointed for the purpose before it was let loose in a world clamorous to do something or to have something done whenever anything is the matter, and, moreover, having greatest faith in the latest fashion. Another function such a body could usefully discharge would be that of selecting, or of compiling if necessary, a text-book of practical use for students and practitioners for each of the different subjects that medicine and surgery embrace. These standardised text-books should be selected for, or revised in, a term of years, and should not be encyclopædic in their nature, and the examining bodies should adopt them as their standard of knowledge in all qualifying examinations.

HOSPITAL TREATMENT AND THE INSURANCE BILL.

The continuous increase in the number of operations performed by surgeons is a matter of common knowledge, but unless one's special attention has been directed to the question one cannot have any idea how great this is, or how from year to year it grows larger and larger. In 1872—the year in which my medical studies began—316 operations were performed in the two general hospitals in Birmingham. Eighteen years later, in 1890—the date of the last annual visit of the Association here—this number had almost trebled, the exact figures being 925; while last year this trebled figure had nearly quintupled again, the number then being 4472. The public operative work at these two hospitals has, therefore, multiplied more than fourteenfold, and that within the period of my own working days. It is interesting to note that the number of beds in the two hospitals has only slightly increased. Each surgeon is doing more operative work to-day than were the united staffs of both these hospitals little more than 30 years ago.

The above figures represent only a portion of the hospital operative work of the city, for in addition to the two general hospitals there are the Women's Hospital, the Children's, the Eye, the Ear and Throat, the Orthopædic, the Skin and Urinary, and the Homœopathic Hospital, and the Workhouse Infirmary, in each of which day by day operations are being performed. Adding their figures to those already quoted gives a total of 10,811 surgical operations performed during one year in the charities of a city containing less than 600,000 inhabitants. After making allowance for patients who come into these institutions from outside the city area, and applying these figures to the 45,000,000 inhabitants of this country, we shall find that not less than 600,000 operations were philanthropically performed last year in the United Kingdom. I desire to call the attention of the author of *The Doctor's Dilemma*, and of all others who appear to be unaware of it, to the fact that this enormous mass of work has been almost gratuitously done, and the bulk of it by men whose reputations are already made. 600,000 does not look much on paper in this age of millions, and may not strike the lay mind as it will the doctor's, but the figure represents a vast expenditure of energy and effort, of strain and anxiety, of time and of self-sacrifice on the part of the men by whose labour and skill this mass of work has been carried out, and the only public recognition of which are votes of thanks for past services, sandwiched in between those to the lady visitors and the chairmen for presiding, passed drearily but unanimously at the tail-ends of thinly attended and spiritless annual meetings of subscribers. Judging by present appearances, this remarkable increase of operations will still go on, and the demands made on the services of hospital surgeons will become greater than ever. How it will end is not difficult to see; the time must arrive when the bulk, if not all, of this operative work ceases to be dealt with by voluntary effort, and men will have to be paid to do the surgical work of the 35 millions of people in this country who at the present time pay practically nothing for the surgical attention they need, and must either provide for themselves or have provided for them.

This is not an occasion for discussing the Insurance Bill, but it may not be out of place for me to refer to an omission from that measure of the greatest importance to the 15 millions of the public who are to be affected by it. I refer to the absence from its clauses of any provision for the active surgical treatment which will be necessarily required by this great body of people. This absence of provision for the treatment of their surgical troubles may be of greater practical consequence, I think, than would have been the absence of provisions for their purely medical ailments; for when a person of this class needs the aid of a surgeon as a rule he needs it badly, and there are only limited sources from which such needs can be satisfied. The necessity for the institutional treatment of many surgical conditions in the working classes will always exist, and provision should be made by the working people themselves or by the State to meet this inevitable demand; for to leave such a matter to the capricious promptings and casual extravagances of voluntary and irresponsible effort is not sound statesmanship as I understand the term.

THE COST OF HOSPITALS.

A matter demanding serious attention is that of the increasing cost of modern hospitals. Their capital outlay on construction and equipment is becoming appalling, and their maintenance charges are correspondingly high. A general feeling exists, I am aware, that as our knowledge advances and our means of dealing with diseases grow greater, so must the cost go up. To some extent this may be true, but it does not cover the whole position. Much of this greater expenditure is due to the tendency seen on every side for public bodies to reckless extravagance. This craving for the lavish spending of other people's money has become a disease, and institutions will at some future time have to be erected for the treatment of persons so afflicted. There is absolutely no need for the spending of large sums of money on the construction of public hospitals; there is no necessity for the sick people in their wards to cost as much as they do. I claim to speak with some authority, if only for the reason that I have worked in charitably maintained hospitals, and in a rate-supported hospital, during the greater part of my life. The object for which all such institutions exist is identically the same—namely, the conversion of sick into sound humanity. The raw material taken into these institutions is alike, the treatment the same, the results identical, but the difference in cost is phenomenal. A charitable hospital now costs from £500 to £800 per bed for construction and equipment, and from 30*s.* to £2 a week per patient for maintenance. The Birmingham Poor-law Infirmary cost less than £90 per bed, and the patients in it 14*s.* 6*d.* per week to maintain. How are these striking differences to be explained? Certainly not by any difference in the quality or the quantity of the work turned out, which are the criteria by which the work of every hospital should be judged, nor by the greater internal comfort of one class of institution over the other. The fact of one being a teaching institution and the other not accounts for something doubtless, but the difference—easy to find—depends on other things than that, but this is not the place to discuss them. I merely wish to call attention to their existence, and to express my own opinion that the sooner all public hospitals become municipally or State supported the better for everybody in any way concerned with them—patients, doctors, and the public alike. Medical teaching and medical research might be better done in institutions altogether controlled by more responsible authority.

We cannot all be leaders in our art, but each can strive to be as the great masters of surgery were in the past. Sir William Bowman, your surgical orator in 1866, who received his general and medical education here, has eloquently said of his predecessors: They were anatomists, they were physiologists, they were pathologists, not by second-hand learning from the tongues and pens of other men, though this they did not despise, but by truth-loving interrogation of Nature herself in all her haunts of health and disease; admitting no veils of limitation to be drawn by fashion or caprice or selfish interest between provinces and things essentially akin, but taking in the whole scope of their art as one great and ample field of noble study and of beneficent activity—one by the unity of Man's body, to which it yields a voluntary and loving service; one by the identity of the methods of research by which the secrets of that body are to be disclosed; one by the common aim and intention of all treatment, internal or external, remedial or preventive; one, lastly, by the simplicity of the moral attitude which should stamp us all as members of one body in our relations towards one another, to individual patients, and to the community among which we labour.

PRESENTATION TO A MEDICAL PRACTITIONER.—Dr. Leslie H. Jones, who has for 28 years practised in Cheetham Hill and in Manchester, has recently determined to retire in consequence of advancing age. At a small representative meeting on July 7th, presided over by the Rev. R. Catterall, rector of Middleton, and held at Tunstead, Crumpsall, at the house of Mr. W. H. S. Craven, an inscribed silver cup, together with a cheque for £775, was presented to Dr. Jones by Mr. Frederick Taylor of Broughton Park. Dr. Jones expressed his thanks to his friends in a very feeling manner. It is extremely pleasant to be able to record such occurrences.

NOTES ON THE EXTRACTION OF CATARACT.[1]

BY HERBERT L. EASON, M.D., M.S. LOND.,
SENIOR OPHTHALMIC SURGEON, GUY'S HOSPITAL.

THE routine operation for the extraction of cataract has not yet been generally agreed upon, and adherents of one or other of the well-recognised methods still claim the superiority of their own choice above all others. The discussion of the subject is rendered difficult to some extent by the paucity of statistics as to ultimate results in long series of cases, and in this connexion it will probably be a disappointment to many that a record of 200 or 300 consecutive cases is not forthcoming even from the vast number operated on by Lieutenant-Colonel H. Smith, who states that he has extracted over 20,000. It is, however, well known that the difficulty of obtaining statistics in India is extremely great, owing to the impossibility of tracing old patients.

The operation for the extraction of the cataractous lens in its capsule as performed by Lieutenant-Colonel Smith has aroused such widespread interest, and the publication of his book will probably lead so many ophthalmic surgeons to try his operation, and so many patients to inquire about it, that it may not be out of place to review the various methods of operation now commonly practised, to attempt to appraise their individual merits or demerits, and finally, to hazard an opinion as to whether the older operations for the extraction of cataract have been found wanting.

It is the opinion of the writer that no single operation is equally suitable for all cases, but that various features, all of which may have an important bearing on the choice of operation, have to be considered. The possible complications and sequelæ of the various operations have to be kept in mind, together with the reasons for which the operation was undertaken; and last, but by no means least, the character of the cataract itself. It has long been recognised that success does not follow equally all operations for the extraction of cataract, however uniformly and skilfully they have been performed; and as the ultimate result of an extraction will depend upon the presence or absence of various important sequelæ, it will be probably more profitable to consider these first, and the various methods of operation later.

Complications following the Extraction of Cataract.

1. *Adhesions of the lens capsule to the extraction scar.*—Mr. Treacher Collins has shown that the irido-cyclitis, sympathetic ophthalmia, and glaucoma which may follow an operation for extraction are often due to the entanglement of the lens capsule in the wound or adhesion to the posterior surface of the cornea. The entangled capsule acts as a foreign body and produces the same inflammation that would follow the implantation of an eyelash or a fibre of cotton-wool. It may also cause inflammation by dragging on the ciliary processes, or glaucoma by dragging the iris forward and narrowing the anterior chamber.

2. *Capsular opacities.*—It is generally agreed that from 30 to 50 per cent. of all cataract operations require a subsequent needling for capsular opacity. Mr. Higgens, in his series of 130 consecutive cataract extractions, notes that he needled 57 out of the 130, some of them more than once, and this may be taken as a fair example of ordinary practice. As a rule the presence of opaque lens matter between the two layers of the lens capsule does not seem to cause any irritation, but a needling operation should be unnecessary in the ideal operation, and if it can be avoided so much the better. It is, of course, well known that the presence of any considerable amount of soft material left behind in the anterior chamber after extraction of the lens occasionally causes iritis, and a very dense fibrous opacity may result. Cases of glaucoma after needling are usually due to previous adhesions of the lens capsule in the wound. The operation of needling has also the disadvantage of breaking down the separation between the aqueous and vitreous. The latter becomes more fluid, and any subsequent operation on the eye is rendered much more hazardous.

3. *Loss of vitreous.*—Loss of vitreous during an operation for extraction, provided that the amount lost is not excessive and that septic infection is avoided, does not seem prejudicial to the ultimate visual results. It is also generally agreed that the effects, if any, are less pronounced when the vitreous is diseased or abnormally fluid than when it is sound.

In the appendix by Captain Lister to Lieutenant-Colonel Smith's book an account is given of a research into 90 cases where loss of vitreous occurred during the operation for extraction of the lens in its capsule. The average length of time which had elapsed since the operation was over three years. No detachment of the retina had occurred in any case, and a large majority of the cases had 6/6 vision or better. A very similar result was obtained last year as the result of a research into some cases under my care at Guy's Hospital in which vitreous had been lost. No untoward results were observed even though several years had elapsed since the operation had been performed. The vitreous, however, is a more stable and satisfactory medium than the aqueous, and if equal visual acuity can be obtained without loss of vitreous it is much more satisfactory. In this connexion it is of interest to note that vitreous was not lost in a single case of Mr. Higgens's sequence of 130.

4. *Prolapse of the iris.*—This occasionally occurs after extraction without iridectomy, most often in those cases in which the nucleus of the lens was small and there was considerable soft material, some of which was left behind the upper part of the iris. The swelling of soft matter due to absorption of the aqueous appears to be a considerable factor in the causation of prolapse. Mr. Higgens found it necessary to remove a prolapse in five cases out of 83 operations without iridectomy, and iridectomy at a later date was required in two more. He states, however, that he leaves small prolapses alone, and it is also the writer's experience that these, provided they do not cause too much eccentricity of the pupil, are best left untouched, and that they do not cause any subsequent inflammation. A large conjunctival flap made at the time of the corneal section is very useful in preventing subsequent prolapse of the iris, as the rapid healing of the conjunctiva prevents any gaping of the cornea and escape of aqueous.

Variations in the Structure of the Cataract.

As has been said above, all mature cataracts are not similar in structure, and it is a great advantage to be able to tell from the appearance of a cataract before operating if it is likely to have a large or a small nucleus, and if consequently there will be little or much cortical soft material. It is well known that amber-coloured cataracts, which in extreme cases are called "black" cataracts, are not really cataracts in the ordinary sense of the word, but are due to a general sclerosis of the lens with no differentiation between cortex and nucleus. They seldom become completely opaque, and never appear white in the pupil, but rather dark grey or brown, and on ophthalmoscopic examination show little definite opacity. As a result the vision never diminishes to bare perception and projection of light, though it may become too deficient for reading and writing. Experience shows that these lenses always shell out extremely easily from the capsule, even when apparently quite immature, and leave little or no soft material behind. The same characteristics may be noticed in those nuclear cataracts which appear whitish, opaque, and almost foamy in the centre, resembling in some degree ice containing small air-bubbles.

Mr. Higgens notes that cataracts with milky or pearly nuclei and striæ scattered plentifully in the cortex, much of which may remain transparent, come away easily, and though immature do not need iridectomy. On the other hand, cataracts which are entirely opaque and very white, though not necessarily hypermature, often consist of a very small nucleus and a large amount of soft material, and Mr. Higgens also notes that in all cases where there is a yellowish nucleus and a cloudy cortex without any definite striæ, that kind of opacity which always appears to be facing one whichever way the eye is looked into, which is ill-defined, and

[1] The writer has referred in this article to the following publications, which should be read by all who are interested in the subject:—The Treatment of Cataract, by Lieutenant-Colonel Henry Smith, I.M.S., Calcutta: Thacker, Spink and Co., 1910. Lieutenant Colonel Smith's Operations in Bombay, by P. P. Kilkelly, M.B., Major, I.M.S., Indian Medical Gazette, May, 1910. Notes on 130 Consecutive Extractions of Cataract without a Failure, by Charles Higgens, F.R.C.S., THE LANCET, April 13th, 1907. Capsular Complications after Cataract Extraction, by E. Treacher Collins, F.R.C.S., Royal London Ophthalmic Hospital Reports, vol. xvi., part iii.

surrounded by a more or less distinct red reflex, the cortex is always sticky and difficult to get away.

With the above considerations in mind it is easier to review the various operations for the extraction of cataract.

Operations for the Extraction of Cataract.

1. *Simple extraction without iridectomy.*—If this operation is successful it is far and away the best both from the point of view of appearance and of visual efficiency. The central mobile circular pupil matches that of the other eye, and after the lapse of a week or two it takes an expert to discover which eye has been operated on. It is of special advantage for those who have prominent eyes, and in whom the upper lid does not cover the upper part of the iris, and as a result an iridectomy would be very apparent. It is the operation to be performed where the extraction is undertaken for the sake of appearances, whether from a social point of view or from the economic necessity of a wage-earner to avoid the disability incurred by the presence of a unilateral cataract, or of an obvious iridectomy. It is also my experience that patients having had both eyes operated on, one with iridectomy and the other without, find that eye most useful which has the complete circular pupil even though the visual acuity of the two as tested by Snellen's types may be equal.

The absence of glare in bright lights and the better definition obtained by the smaller pupillary aperture make the eye more efficient for all purposes and under all conditions. It is extremely rare to get any involvement of the capsule in the wound after the operation, as the iris draws all tags of capsule back to the centre and away from the corneal section, and for the same reason loss of vitreous is less likely to occur than when iridectomy has been performed. A further advantage of the simple extraction is that it requires the minimum interference with the eye, and can be done with the fewest instruments.

Having learnt the technique of the operation from Mr. Higgens, the writer follows his methods as described in his paper. No speculum is required, and the necessary fixation can be obtained by passing a stitch through the conjunctiva below the cornea and getting an assistant to hold it down on the cheek. If the knife is properly sharp it may be passed through the anterior chamber from side to side without moving the eye; no forceps are required for fixation and the eye can be steadied on the edge of the knife while the section is being made. The lens is expressed by the two thumbs, one operating upon the lower part of the globe through the lid and the other making counter-pressure on the upper part of the globe. The iris usually returns at once, but if necessary can be replaced with a repositor. Should it show any tendency to prolapse an iridectomy can be done subsequently to the extraction instead of before. Thus the only instruments really required in many cases are a Graefe's knife and a capsule hook, and the latter *can* be dispensed with if the capsule is opened with the point of the knife as it passes through the anterior chamber, a manœuvre I first saw performed by Mr. Stanford Morton at the Royal London Ophthalmic Hospital.

The only disadvantages of this operation are, the comparative difficulty of removing soft material which may get up under the upper margin of the iris, the danger of prolapse and the subsequent formation of a web. But these sequelæ may be avoided by selecting for the operation only those cases of cataract mentioned above, which have very little soft material and a large nucleus.

2. *Extraction with iridectomy.*—The iridectomy may be performed either as a preliminary operation or at the same time as the extraction. The former course has the advantage of giving the operator some idea of the behaviour of his patient before he attempts the more serious task of removing the lens, but it has the disadvantage that the iridectomy wound cannot be subsequently anæsthetised with cocaine, and the corneal section at the second operation may be painful. It is more usual therefore to perform the iridectomy at the same time as the extraction.

The advantages of iridectomy are that the soft material is more easily evacuated than in the simple extraction without iridectomy, and that there is no danger of a subsequent prolapse of the iris.

The disadvantages are that prolapse of vitreous is more likely to occur during the operation, and that the lens capsule, unless carefully replaced, may become incarcerated in the wound. In order to obviate this complication Mr. Treacher Collins devised his method of removing the anterior lens capsule with forceps instead of tearing it with the sharp hook. He says:—

> As a result of his experience the writer thinks it best after a small iridectomy has been performed to introduce the capsule forceps closed, to a position opposite the centre of the lens, then to allow the blades to separate to an appropriate extent, and while separate, to depress them slightly backwards so that their teeth penetrate the capsule. At the forceps being again closed the capsule can often be seen to ruck up on the surface of the lens and a slight, lateral, side to side movement should then be made before withdrawing them from the eye. This lateral, side to side movement serves to detach the anterior capsule and to prevent the withdrawal of the lens in its capsule, which may occur if a pull outwards is at once made.

The advantage of this procedure is not only that no anterior capsule is left to become entangled in the wound, but also that the aqueous obtains free access to any soft material that may be left behind, and a web is much less frequent than in cases where the capsule has been merely lacerated.

Mr. Treacher Collins notes that of 200 cases operated on by him in this manner subsequent records of 145 were obtained, and that 51, or 25 per cent., obtained 6/6, or 6/6 partly, without needling. This percentage of normal vision with one operation is certainly much higher than that recorded by any other method of extraction, excluding Smith's operation. It must be remembered, however, that needling may be ultimately required, even though the anterior lens capsule has been removed, not by reason of the existence of an opaque web, but because the posterior capsule may, though transparent, become wrinkled and prevent the formation of a well-defined image. After an iridectomy the pupillary aperture is large, and though the upward iridectomy is hidden by the upper lid, there is no doubt that patients suffer considerably from glare in bright lights.

3. *Extraction of the lens in the capsule.*—The operation for the extraction of the cataractous lens in its capsule has in recent years received such powerful advocacy from Lieutenant-Colonel Smith of Jullundur, and he has made such important modifications in its technique that it now goes by his name, though of course it has been frequently performed previously, both intentionally and unintentionally. Space will not permit here of giving a detailed description of the operation, but everyone who is interested in ophthalmic surgery should read his book, which is amply illustrated, and in which the *pros* and *cons* of the various operations for cataract are dealt with at great length.

Briefly it may be stated that in Smith's operation, after an iridectomy, the lens is expressed bodily in its capsule. The rupture of the suspensory ligament is accomplished by pressure with a blunt hook on the lower part of the cornea, the lens in its capsule dislocating first in the wound. Escape of vitreous from the gaping of the wound is obviated as far as possible by making the patient look up instead of down during the expression of the lens, the upper eyelid being lifted from the globe by a hook.

The advantages claimed for this operation are that it is quite as safe as the ordinary method of extraction, and that all subsequent operations for after-cataract and all capsular complications are avoided by the bodily removal of the lens capsule, and that escape of vitreous, which, it is generally agreed, is not infrequent, has no detrimental effect upon the subsequent vision.

The operation is recommended by Lieutenant-Colonel Smith both for mature and immature cataract, but in his advocacy for its adoption for immature cataract he dismisses all methods of artificially ripening the unripe lens with very brief consideration. In discussing trituration, or iridectomy with massage through the cornea, he says: "In my observation it has no influence on the immature cataract if the massage be done with a justifiable degree of pressure, that is pressure which will not dislocate the lens." With this statement the writer must entirely disagree. He is constantly triturating lenses in hospital practice and can assert that it is a matter of common experience that trituration of the lens through the cornea usually produces complete opacity of the lens in from three to four weeks. The writer has never dislocated the lens, and vitreous has never been lost at the subsequent extraction.

Trituration has also the advantage that the soft cortical material which is found at the extraction is never sticky and can be easily and completely expressed with the nucleus by gentle pressure on the cornea. Subsequent capsular opacities are infrequent. The only objection which has been

raised against trituration is that in unscrupulous hands it may lead to malpractice, as at the preliminary operation it is very easy to give a patient a cataract even if one was not present beforehand.

Immature cataracts can also be extracted with safety after removal of the anterior lens capsule with forceps by the method adopted by Mr. Treacher Collins. The aqueous has free access to the lens material left behind, and it is soon absorbed.

It wants to be thoroughly understood, therefore, by all those who are suffering from immature cataract that it is not necessary in these days to wait until a slowly growing cataract matures, whether an extraction of the capsule or an ordinary extraction is proposed. The sole criterion is the amount of vision and its importance to the patient. Directly vision has failed in both eyes so that the patient cannot read or write with comfort an extraction can be undertaken with safety.

In dealing with mature cataract also Lieutenant-Colonel Smith is an ardent advocate of his method as the best operation for senile cataract under all conditions, and he certainly has had a vast experience, and ought to speak with authority. Some Indian ophthalmic surgeons, however, who have had some opportunity of seeing more of his work than oculists at home, are not in agreement with him, notably Major Kilkelly of Bombay. At Major Kilkelly's invitation, Lieutenant-Colonel Smith performed 23 cataract operations at the Sir Cowasjee Jehangir Hospital, Bombay, in February, 1909. The results of these operations are detailed in the *Indian Medical Gazette* for May, 1910, and show that of the 23 cases incarceration of the iris occurred in 5, capsule tags in the wound in 4, vitreous opacity in 9, and iritis in 7. The visual results cannot compare with those obtained by Mr. Higgens or Mr. Treacher Collins, and Major Kilkelly himself says that he has performed some 600 extractions of the capsule, but that he has given up the operation as a routine procedure, being convinced that the best interests of the patient would not be considered if it were done, except in very exceptional cases. Major Kilkelly remarks with reference to Lieutenant-Colonel Smith's series that for the extraction of the lens in the capsule it seemed in some of the cases at least that the pressure necessary was excessive. Many lenses shelled out with the utmost ease; in others it was only the undoubted determination of the operator which brought about the desired result and caused a rupture of the capsule or escape of vitreous.

In the same number of the *Indian Medical Gazette* there is also an article on Smith's operation which reviews a number of publications dealing with the operation, and the opinions of the various writers appear to be divided, several being still unconvinced of the safety of the operation.

Ultimate Vision.

It may be of interest to survey the ultimate visual results as recorded in the papers which have been mentioned in this article. Out of 115 cases of Mr. Higgens's 130 who were not precluded from good vision by previous iritis, choroiditis, or other diseased conditions, 8 obtained 6/6; 33, 6/9; 39, 6/12; 24, 6/18; 7, 6/24; 3, 6/30; none, 6/60; and $1 < 6/60$.

Mr. Treacher Collins gives no particulars as to the vision of all his cases, but notes that 25 per cent. got 6/6 without needling.

As has been said above, Lieutenant-Colonel Smith gives no statistics as to vision in any series of his own cases, but Captain Lister gives the visual results of 61 cases of loss of vitreous: 6/3 in 4, 6/3·5 in 6, 6/4 in 4, 6/4·5 in 5, 6/5 in 4, 6/6 in 33, 6/8 in 2, 6/9 in 3. Captain Lister makes the note that in India, owing, he thinks, to the better light and clearer atmosphere, patients who come to him for examination usually read a line or two more of Snellen's test types than they do in England. He finds that very many British soldiers read 6/3·5 quite easily.

On the other hand, the visual results of the 23 cases operated on by Lieutenant-Colonel Smith for Major Kilkelly in Bombay show a very different result. One case only got 6/15; 2, 6/20; 7, 6/30; 3, 6/40; 4, 6/60; and 6 less than 6/60. It will be seen, therefore, that even though by Smith's operation some extremely good results may be obtained one may also get some very poor ones.

It appears, therefore, that the extraction of the lens in its capsule is not yet being universally adopted as a routine operation for the extraction of cataract, and that it has been tried and rejected by many skilful operators as being too risky, and in view of the other facts quoted here it cannot be said that the results of extraction of cataract performed in the old way are unsatisfactory. It is the writer's own experience that nearly every ophthalmic surgeon of his acquaintance to whom he has put the question has replied that if he were going to have an extraction performed on himself he would not select extraction in the capsule, but would be content with the ordinary extraction, with or without iridectomy.

It has been the writer's object in this article to show that in his opinion no single operation can be adopted for all cases as a matter of routine. In selected cases a simple extraction without iridectomy is undoubtedly the best. In cases where there is likely to be much soft material removal of the anterior lens capsule with forceps will give extraordinarily good results, and it is evident that in skilled hands the older methods of extraction of cataract are quite as efficient as, and probably safer than, extraction in the capsule. Time alone will show whether the latter operation will be generally adopted or whether its success depends alone on the peculiar dexterity of Lieutenant-Colonel Smith himself.

THE APPENDIX, ITS RELATION TO THE CAUSATION AND SURGICAL TREATMENT OF AFFECTIONS OF THE ADNEXA.[1]

BY H. MACNAUGHTON JONES, M.D., M.CH., M.A.O. Q.U.I., F.R.C.S. IREL. & EDIN.

THE object here is briefly to review, alike from the pathological, clinical, and operative standpoints, the influence which our present knowledge exerts on the diagnosis and operative treatment of appendical complications in affections of the female genitalia. The importance of the subject is illustrated by such cases, amongst others, as the following:—In a child, aged 10, an appendical abscess with the appendix found adherent to the pelvic floor; in a child, aged 11, the inflamed and diseased appendix adherent to the ovary; pyosalpinx with a long appendix adherent to a diverticulum of the bowel at the left side; an adnexal lesion in which the rudimentary appendix, reduced to a thin cord, was constricting the bowel; a case in which the cystic ovary, tube, and appendix, with concretions, were matted together; a retrocæcal abscess with slough of the appendix (only discovered post mortem) following curettage and resection of cystic ovaries, performed for menorrhagia and dysmenorrhœa associated with endometritis, without any history or suspicion of appendicitis; some cases in which subsequent appendectomies had to be performed after cœliotomy for adnexal disease.

There is the interesting question of the course of the inflammation from ovary to appendix, or *vice versâ*. The "appendiculo-ovarian" ligament, first described by Clado, is by some authorities (as, for example, Treub, Dutilh, Olshausen, Krönig, and Döderlein) accepted as the track by which the infection travels. This ligament (springing from the "infundibulo-pelvic ligament"), according to these and other gynæcologists, contains nerves, vessels, and lymphatics. Parametritic disease may extend along it to the cellular tissue between the mesentery of the cæcum and the iliac mesentery of the appendix, or in the opposite direction, the primary condition (according to Krönig) being a chronic adhesive appendicitis. This leads to suppurative processes which extend along the lymph tracts, or there may be a direct rupture from the one structure into the other. Hartmann (Paris), who has discussed this question exhaustively, believes, on the other hand, that this ligament is simply a fold of peritoneum passing behind the meso-ovarian and does not form any vascular or lymphatic link between the ovary and appendix. He (Professor Hartmann), with others, accounts for the spread of the inflammation either by direct contact of the diseased structures one with the other

[1] Abstract of a valedictory address to the Obstetrical and Gynæcological Section of the Royal Society of Medicine.

or by the serous peritoneum. As the result of inquiries for the purpose of this paper made from ten of the university anatomists of the United Kingdom, one arrives at the conclusion that British opinions vary as to the presence and nature of this structure. It does not appear to be always present; it may be a peritoneal fold not containing any lymph vessels; it is distinct from the appendiculo-pelvic ligament. Professor A. M. Paterson (Liverpool University) has made for me a recent drawing from a subject in which the infundibulo-pelvic ligament is clearly seen, and which, he says, contains the ovarian vessels, nerves, and lymphatics, and is constantly present, extending from the pelvic brim to the outer end of the Fallopian tube. It would thus appear that there are different routes by which the inflammation may travel, and that it often may be the result of direct contact. There may also be (as demonstrated by Crossen) adhesions between the appendix and cæcum, and through exceptional mobility of the cæcum, the consequent infiltration, simulating an intro-cæcal growth, may drop down into the tubo-ovarian region. He has had two such cases.

As to the important question of the relative frequency of appendical complications in adnexal disease, statistics vary, partly because some follow the vaginal route in operations, and hence do not examine the appendix, and, secondly, because the pathological conditions present in the appendix (Krönig) escape notice when it is not removed. Krönig says that a right-sided pyosalpinx in a young patient in whom there is neither clinical nor bacteriological evidence of tuberculosis or gonorrhœa, is almost certainly due to infection of the tube from a primary appendicitis. Abscesses in Douglas's pouch are often due to the same cause. From the statistics (quoted) of a very large number of laparotomies performed on women for adnexal disease, we may conclude that on a moderate calculation some 12 per cent. have appendical complications. Some authorities, as, for instance, Krönig, Peterson, and Hermes, put it at 50 per cent. Howard Kelly, in his recent "Medical Gynæcology," says that in the ten years previous to 1904 he removed the appendix in 240 cases, the majority of which were combined gynæcological and appendical affections. He comments on the predisposing influence of torsion of an ovarian cystoma, the greater frequency of appendical involvement in ectopic gestation, and its rarity in myomata. On the line of practice pursued by continental and American, as well as some British gynæcological surgeons, I have had definite answers to these two queries from all to whom I have written: "Do you examine the appendix in every case of cœliotomy?" "Do you always remove it, and if not under what conditions do you do so?" These authorities include Howard Kelly, E. Montgomery, Polk, J. B. Murphy, Boldt, William Mayo in America; Lapthorne Smith in Canada; P. Zweifel, Zurhelle (for Professor Fritsch), Bumm, Schötlander, Wertheim, Döderlein, Schauta, Schultze, Dmitri de Ott, Mangiagalli, Jacobs, Hartmann, and Pozzi on the Continent. At home I have ascertained such representative views as those of Dr. E. H. Tweedy, Dr. H. Jellett, Dr. F. W. Kidd, Dr. J. Campbell, Sir Halliday Croom, Dr. J. M. Munro Kerr, Mr. Christopher Martin, and Dr. Murray (Liverpool). The unanimous opinion of all is that the appendix should be examined in any cœliotomy for adnexal disease. Krönig and Montgomery remove the appendix whether it be diseased or not, Kelly and Boldt in nearly all instances; Lapthorne Smith inclines to the same course, also Schultze, unless there be some special contra-indication. All the others named remove it only when there is evidence of adhesion or some morbid condition, or unusual length.

[Dr. Macnaughton Jones here dealt with diagnosis, discussing the relative value of McBurney's and Lanzs's points, the classical clinical signs of appendicitis as compared with salpingitis, Olshausen's diagnostic distinction, and the pathological evidences which point to the original source of the inflammation, as also the necessity for the bimanual and recto-vaginal method under anæsthesia. He continued:—]

Several authorities, since MacLaren drew special attention to the causal relationships between appendicitis and dysmenorrhœa, have pointed out the correlation which exists between the two, notably Soupault and Jouaust. Here, again, the presence of the more characteristic signs of appendicitis, such as gastro-intestinal symptoms or muco-colitis, and the localised character of the pain together with elevation of temperature in the rectum as compared with that in the axilla, and abdominal rigidity, will materially assist us in coming to a conclusion.

As to the method of operation, the abdominal route in these ambiguous cases appears decidedly preferable to the vaginal, and also the median incision. If, however, the abscess be localised in Douglas's pouch, a posterior colpotomy for many reasons is the best method of attack.

On the entire consideration of the subject I think it is clear that the appendix should be examined in every case of cœliotomy for adnexal disease. This equally applies to the left adnexa as to the right. When the abdomen is opened for a grave appendical trouble the adnexa should be examined. The appendix should be removed in every instance where any abnormality or disease is found or if it be of unusual length, also if from the character of the operation there is a probability of further adhesions forming which may involve the appendix. The severity of the operation, however, will always have to be taken into account, and the influence its prolongation may have in lessening the chances of the patient's recovery.

Harley-street, W.

RUBELLA OR MEASLES?

BY DONALD W. C. HOOD, C.V.O., M.D. CANTAB., F.R.C.P. LOND.,
CONSULTING PHYSICIAN, WEST LONDON HOSPITAL.

THE following case presents some points of interest to those who share with the writer the belief that rubella is probably but a variety of measles.

A young married woman, aged 27 years, who had never suffered from any form of measles, on Monday, Jan. 23rd, felt poorly, with headache and general aching pains, the temperature being 102° F. She remained in much the same state, and the temperature continued to be raised until I saw her on Thursday afternoon, Jan. 26th, the only symptoms of illness then being a temperature of 102°, a general feeling of malaise, and a slight but persistent headache. The following morning I found practically the same condition, which remained without further symptoms until Sunday, Jan. 29th, when on waking in the morning a rash was found on the face and neck. The eyes were suffused, there were a dry irritable cough and a characteristic rash of measles, with a temperature of 102·4°. During the next 24 hours the rash had much increased, and on the morning of Monday, the 30th, the face was swollen and contorted with a confluent eruption, which had by this time invaded the arms, chest, and abdomen. There was also much rash on both hard and soft palate. No Koplik's spots were present. One small painful gland on the mastoid could be felt. The cough was constant but the temperature had fallen to normal and remained so during the entire eruptive period of four days. The rash invaded all parts of the body and was typical of measles. From first to last, with exception of the irritable cough and injection of conjunctivæ, there was no sign of coryza or catarrh.

I believe that anyone with experience of all kinds and sorts of measles would have found it difficult to place this case in the appropriate class. Within the past few months there have been a large number of cases of measles, not only in the London area but throughout England, and I understand that in many instances the type is atypical. I have been informed by four experienced practitioners that they have been attending patients with whom they have found it impossible to differentiate between so-called rubella and measles.

In the Epidemiological Section of the Royal Society of Medicine the subject of rubella was discussed in February, 1908, and one of the speakers referred to a little pamphlet of mine on the etiology of rötheln, in which he stated that I had expressed the view that rubella is an "attenuated form of measles." Never for one moment have I held such an opinion. I consider that rubella and its congeners are varieties of measles, and, far from being always of an attenuated form, may occur with extreme severity. Those who describe rubella as being of a mild character must surely forget the description of a small epidemic alluded to by the late Dr. Cheadle in a paper read before the International

Congress of Medicine held in London in 1881. This epidemic, considered by me at the time to be caused by very severe measles, was regarded by Dr. Cheadle as due to rubella, and he formed this opinion mainly from the fact that in a large number of instances those who suffered from the attack had previously suffered from ordinary measles. Such an argument in favour of specific difference is of little value or weight, as we know that it is quite common for individuals to have two or more attacks of ordinary measles. Although we may assume that an attenuated virus may produce an atypical clinical condition, with very marked variation or even suppression of symptoms, it has to be considered on an entirely different footing to a virus that has undergone variation and given rise to an illness atypical to the parent or ordinary form of the disease. Such a variation may tend to increase of virulence and symptoms may so assume a more intense form. I have seen a nearly white sparrow hopping about in the roadway. This bird can scarcely be called an attenuated sparrow, but it undoubtedly does show some variation from the ordinary type. Some of those who read these lines may love our wild flowers, and they may have been puzzled when first seeing Butcher's broom, that curious shrubby plant with the prickly pseudo-leaves and berries so suggestive of our common holly. One would hardly associate it with the gentle, delicate lily of the valley, and yet it is one of its sisters, and we must classify it as a lily.

Under the genus measles would I class rubella, coming before us, as it undoubtedly does, under many a form and aspect, and until the bacteriologist supplies us with more definite information I shall believe that the balance of clinical evidence is in favour of "German measles" being only a variety of the common type.

Green-street, W.

A SUCCESSFUL CASE OF OVARIOTOMY AND CÆSAREAN SECTION PERFORMED ON THE SAME SUBJECT AT ONE SITTING.

BY H. B. MYLVAGANAM, F.R.C.S. ENG.,
SURGEON TO VICTORIA HOSPITAL, BANGALORE.

IT is not often that an opportunity presents itself of carrying out two major operations on the same subject at the same time, and the successful performance of the operations which I here describe illustrates forcibly the physical endurance of Indian women, who lead a simple life. The notes of the following case will perhaps be of some interest, and the rarity of the position is my plea for publishing them.

On August 9th, 1910, a Hindu female, aged 30 years, was admitted into Victoria Hospital, Bangalore, with an enormously distended abdomen. The history of the case showed that the patient had menstruated at the age of 14 years and had had no menstrual troubles. She had not menstruated for the past eight months. She was married and had borne two children. She had felt sensations in the abdomen resembling fœtal movements. She had never had any abortions. She had noticed that for the past few years the abdomen was becoming larger, for which she had been tapped at the Mysore Civil Hospital four times and fluid had been drawn out.

Upon admission the patient was found to be much emaciated and anæmic. Marks of old tappings were visible over the linea alba between the umbilicus and pubes. The abdomen was enormously distended, so much so that she was unable to lie down comfortably, but sat up in a semi-recumbent position the whole time. The abdominal wall was much thinned out. There was dulness over the front of the swelling, as well as resonance in the flanks. A distinct fluid thrill was felt over the swelling on palpating its upper portion, but a hard lump was felt on the left side between the umbilicus and the left Poupart's ligament Owing to the tension of the abdomen the nature of this hard lump and its relation to the cystic swelling could not be made out. The breasts were flaccid, the areolæ were slightly pigmented, and a thin serum exuded on squeezing the nipples. The cervix was softened, and the os uteri was dilated to the extent of admitting the tip of a finger. There was no history of morning sickness. No œdema of the lower extremities was present. The urine was normal.

The case was diagnosed as one of ovarian cyst complicated with pregnancy, but the duration of the latter was not certain, as the uterus could not be clearly defined abdominally.

On August 13th abdominal section was performed, and a large thin-walled cyst containing smaller cysts was found occupying the upper part of the abdomen, reaching from the ensiform cartilage as far as the umbilicus, and an enlarged uterus was lying below it, with the fundus directed to the left. The appearance of these two swellings was characteristic. The cyst was pearly white and the uterine swelling was of a reddish colour. The cyst, which involved the right ovary, was tapped and removed. Owing to the advanced state of the pregnancy, it was thought advisable to perform Cæsarean section for the following reasons: (1) In case the mother had a premature delivery in consequence of the operation, an abdominal wound would be inconvenient for the expression of the placenta, &c.; (2) in the event of peritonitis or any other accident to the mother incidental to an abdominal section, the safety of the fœtus would be endangered; and (3) because a viable fœtus was likely to be delivered. The uterus was therefore divided in the middle and a viable female fœtus, about 8 months old, was removed. The uterus was sutured up by double layers of suture, the first layer passing through the peritoneal and muscular coats without entering the cavity, and the second row through the peritoneal coats only.

The patient made an uneventful recovery in spite of the double operation, which occupied about 1 hour and 25 minutes, and mother and child were discharged from hospital in one month after the operation.

Bangalore.

A FATAL CASE OF ACUTE MERCURIAL POISONING.

BY A. W. BURTON, M.B., CH.B. EDIN., L M. DUB.,
HOUSE SURGEON, BRISTOL GENERAL HOSPITAL.

THE patient, a single woman aged 26 years, was admitted into the Bristol General Hospital on August 21st, 1910, under the care of Dr. Carey Coombs, who was at that time in charge of Dr. J. Odery Symes's beds.

At about 1 P.M., shortly after a meal, the woman, who had previously attempted suicide, swallowed 44 grains of corrosive sublimate in the form of soluble tablets. She was seen about an hour later and presented a cyanosed appearance, with cold clammy hands and face. Vomiting began almost immediately after she was seen. The vomitus, which at first closely resembled the white of an egg, soon became bluish in colour, the solid constituents of the vomit being stained blue as well as the fluid part. This was due to pigment present in the poison swallowed. About 15 minutes after the onset of vomiting the patient was seized with severe abdominal pain, and profuse violent diarrhœa set in suddenly, the motions being greenish and very slimy. Both vomiting and diarrhœa became persistent in character. The pulse became rapid and weak, and the cyanosis was soon replaced by pallor, the patient passing into a condition of marked collapse. The abdomen was flaccid and moved very little during respiration. There was no rigidity, tenderness, or distension present. The hepatic and splenic dulness remained normal throughout. After the patient had vomited several times the vomitus became blood-stained, but no shreds of mucous membrane were seen in it. The pupils remained equal and normal in size and reacted to light.

During the following night the patient vomited blood-stained material at intervals; still no shreds of mucous membrane were seen. Abdominal pain continued to be severe and paroxysmal in character, causing her to cry out. There was marked odynphagia. The diarrhœa became less profuse, but continued. Vomiting persisted and the patient complained of a choking sensation in the throat, and at times became dyspnœic. There was complete suppression of urine and only one fluid drachm of serous blood-stained fluid was drawn off from the bladder, which showed no signs of distension. Acute vaginal pain was present, and the vulva was found to be swollen and red, slight vaginal discharge being present. Tremors were present in the limbs, but no convulsions

took place. Later the actions of the bowels became very frequent, the motions, which were small in quantity, being very offensive and containing numerous shreds of foul-smelling necrotic mucous membrane. Each motion was blood-stained. The gums became very red and the lips slightly swollen. The tongue was very red, dry, and brown-coated on its dorsum. The pharynx was red and congested, and patches of excoriation appeared on the buccal mucosa. Salivation was not a conspicuous feature. The abdomen became retracted and its movement during respiration much diminished. No urine was passed. The bladder remained undistended and the catheter was passed on several occasions without result. Diarrhœa persisted, but vomiting occurred much less frequently. Tremors were noted in the jaw and hands. The odynphagia and also the abdominal pain gradually disappeared. The abdomen became somewhat distended, moved more freely, and gurgling sensations were produced during palpation. There was slight resistance over the upper part of the abdomen, but little tenderness. No signs of perforation could be detected. The vaginitis became less marked under treatment and no sloughing occurred. The patient gradually became drowsy and ceased to complain, the tongue and lips became more inflamed, and the anuria was most persistent. The temperature was practically subnormal throughout, ranging between 95·5° and 96° F. Drowsiness gradually passed into coma, and she died on August 28th at about midday, seven days after taking the poison.

The symptoms were probably modified to a considerable extent by the adoption of prompt and appropriate treatment, which consisted in early lavage of the stomach, the administration of antidotes and stimulants, and attempts to assist elimination, together with the treatment of the various symptoms as they arose.

Post-mortem examination.—Swelling of lips and buccal mucosa. Tongue swollen. Fauces inflamed and red. A small hæmorrhagic ulcerated area on the anterior surface of the œsophagus 2½ inches from the cricoid cartilage; remainder of œsophagus free from ulceration but congested. Thymus: trace. Thyroid: slightly enlarged. Pleuræ: slender adhesions and excess of fluid on both sides; tracheitis. Lungs: hypostatic congestion in both bases; mild bronchitis. Pericardial sac: normal. Heart: slightly enlarged; heart muscle pale, friable and soft; valves, endocardium, and coronary arteries normal in appearance. Abdomen contained several ounces of blood-stained non-coagulable fluid; no adhesions; no perforation of any hollow viscus. Liver somewhat pale. Gall-bladder filled with bile; mucous membrane quite healthy. Bile-ducts and Vater's ampulla normal. Spleen not enlarged, good colour and normal consistence. Pancreas and ducts normal. Suprarenal capsules normal. Kidneys: both slightly enlarged. Relative thickness of cortex and medulla as 1: 3. Cortex pale and streaked with congested lines in all directions. Glomeruli easily seen on section. Calyces, pelves, and ureters much injected and filled with a semi-solid brownish-coloured material. The microscope revealed the presence of intense regressive changes in the renal parenchyma widespread in distribution. Bladder: mucous membrane much injected; its cavity contained some semi-solid brownish material but no urine. Uterine appendages: normal; a recently ruptured Graafian follicle in the left ovary; no sloughing in the vagina. Alimentary canal: ulceration of œsophagus as mentioned previously. Stomach normal in size and shape; mucous membrane yellowish in colour with absence of rugæ. On the greater curvature about 2 inches from the pyloric orifice a black escharotic ulcer about the same size as a half-crown. Pylorus normal. The intestines showed signs of most intense irritation. Mucous membrane of duodenum much injected; no ulcers present. Jejunum and a large part of the ileum almost normal in appearance; mucous membrane yellowish in colour and hyperæmic. Lower part of ileum, cæcum, and whole large intestine completely involved in a continuous series of escharotic ulcers of the most virulent type and greyish-black in colour.

Briefly, the case is worthy of record because a dose of 44 grains of mercuric chloride, taken in a very concentrated form, failed to prove immediately fatal. The poison was taken shortly after a full meal, and was, therefore, so far diluted that its irritant action on the digestive mucosa was not quite intense enough to prove rapidly fatal. At the same time, however, the end was only delayed until the poison, taken in a readily soluble form, quickly dissolved in the stomach, and freely absorbed into the circulation, had time to produce the evidences of general systemic mercurialism in a very intense degree. Although we were at first encouraged by the patient's temporary recovery from the stage of gastro-enteritis, it soon became clear that her system was so saturated with mercury that we had no justification in hoping for her recovery.

I am much indebted to Dr. Carey Coombs and to Dr. Symes for their help and for permission to publish the notes of the case.

Bristol.

Medical Societies.

EDINBURGH OBSTETRICAL SOCIETY.

A Contribution to the Theory of Enzygotic (Mono-chorionic) Twins.—Mongolism.—Two Rare Pelvic Tumours.

A MEETING of this society was held on July 12th, Dr. F. W. N. HAULTAIN, the President, being in the chair.

Dr. D. BERRY HART read a paper entitled, "A Contribution to the Theory of Enzygotic (Mono-chorionic) Twins." By enzygotic twins were understood twins developed from one zygote (fertilised ovum). The most striking instance of these was identical twins, where the similarity was complete, even to the finger-prints (Wilder). It was further noteworthy that all twins derived from one zygote were of the same sex. In considering the causation of such anomalies Dr. Hart advanced the theory that one must go back to the zygote itself, and looking on it as containing the determinants for the organs of the developed infant he suggested that in enzygotic twins there might be a complete or incomplete doubling of the determinants, and then a complete segregation of these into two groups. In identical twins the doubling and segregation were complete; in the other deformities the doubling was incomplete, and segregation thus gave a complete twin and an incomplete one. Thus if an acephalic twin was present along with a normally developed one the determinants for the head were not doubled, and thus the acephalic result on one side.—Dr. J. W. BALLANTYNE discussed Dr. Hart's ingenious theory of origin of double monsters, identical twins, and allantoido-angiopagous twins. It was now about 20 years since he had contributed several articles on these curious monstrosities, and whilst he had admired the ingenuity of Dr. Hart's theory he did not see how it explained such mixed types as the paracephalic twin without a heart. He agreed with Dr. Hart as to the probability that these twins were formed in the germinal period of ante-natal life. Dr. Hart deserved credit for the way in which he was applying Mendel's theory to the science of development.—Dr. JAMES RITCHIE asked if it were purely theory or had Dr. Hart any facts to support the argument that there was a doubling of the determinants.—Dr. W. FORDYCE and Dr. B. P. WATSON also engaged in the discussion.—Dr. HART, in reply, stated that there had been hundreds of exact observations that all organs of the body might be lost. In cases without a heart there was an absence of determinants. They must speculate to a certain extent and then see if the speculation fitted in as an explanation of certain facts.

Dr. H. M. CHURCH read a paper on Mongolism, and stated the case of a Mongol girl, born of a primiparous mother, who had a bicycle accident about ten days after conception. Both parents were young and healthy, and had a subsequent family history of three healthy boys. Mongolian primiparous birth was very rare, and Mongols were often the product of parents with disparity in age or of a mother exhausted by child-bearing. In this case there was no indication of parental alcoholism, syphilis, or tuberculosis.—Dr. HART thought that traumatism was one of the best explanations of the condition.—Dr. BALLANTYNE referred to the effect of traumatism on the embryo. It was known that when eggs were shaken by a railway journey and immediately incubated on arrival there would be a number of abnormal chicks, but if the eggs were allowed to rest some days and then incubated there would be the usual number of healthy chicks. But it was difficult to understand how

traumatism could act on the human embryo, packed away practically safe from a shock.—Dr. H. OLIPHANT NICHOLSON also took part in the discussion on mongolism.

Dr. A. H. F. BARBOUR and Dr. WATSON read a paper, illustrated with lantern slides, on Two Rare Pelvic Tumours—Perithelioma of the Uterus and Perithelioma of the Fallopian Tube. The former occurred in a parous woman, aged 58 years. The symptoms were watery and fœtid leucorrhœa and a return of uterine hæmorrhage ten years after the menopause. The tumour, removed by hysterectomy, was of the size of a five months' pregnancy. On section it was of a yellowish colour and contained many hæmorrhages very like an ordinary sarcoma. Microscopically a great part was found to be necrotic, but throughout the typical structure of a perithelioma could be seen. The tubal case was a woman, aged 51, unmarried and nulliparous. She had a swelling in the lower part of the abdomen and a hæmorrhagic vaginal discharge. Free fluid was found in the abdomen and secondary nodules were present all over the peritoneum. The left tube was the seat of a tumour. The patient died 11 days after the operation. The tumour of the tube presented the same characters as the uterine one described above.—The PRESIDENT said he showed a uterine specimen to the society recently, and though the uterus and upper part of the vagina had been removed it had already returned within three months and was spreading rapidly. These tumours were evidently of extreme malignancy.

Reviews and Notices of Books.

An Introduction to Bacteriological and Enzyme Chemistry. By GILBERT J. FOWLER, D.Sc., F.I.C., Lecturer in Bacteriological Chemistry in the Public Health Department, Victoria University of Manchester; Examiner in Biological Chemistry to the Institute of Chemistry of Great Britain and Ireland. London: Edward Arnold. 1911. Pp. 328. Price 7*s.* 6*d.* net.

WE cordially welcome this book because it deals in easy stages with an ever-widening and interesting subject—the rôle of bacteria and ferments in so many departments of life. The development of biological chemistry has been very extraordinary during recent years, and the importance of its study becomes more apparent as fresh instances are revealed of the value of its applications in matters of great practical moment. "A knowledge of it is now necessary for the scientific conduct of many industrial processes of great magnitude," says Dr. Fowler, "..... apart from its well-known applications in the fermentation industries, a scientific understanding of this branch of chemistry is likely to exercise considerable influence upon the future development of agriculture. ..... Recent advances in sanitation, especially the provision of pure water and the inoffensive disposal of sewage, call for the coöperation of the engineer and the biological chemist." To these reasons, advanced by Dr. Fowler as though to justify the appearance of his book, we may add another which makes the study of biological chemistry of supreme importance—namely, the share which it has taken in advancing our knowledge of the great vital processes of the human machine. The whole superstructure of modern medicine would never have been raised if the foundations had not rested on bio-chemical considerations.

Dr. Fowler opens his subject with a short chapter on chemical action in living matter, which necessarily introduces the reader to a consideration of catalysis, colloids, and osmotic pressure. Next comes a clear survey of bacteriological technique, and then the author evidently found he could not proceed further with his subject until the principles underlying organic chemistry had been discussed, a discussion which culminates in an account of the chemistry of the sugars and starches. Then the reader gets fairly into the subject by following the experimental details illustrating the action of amylase (diastase) upon starch. This naturally leads to a chapter on the alcoholic fermentation of sugar, and later the acid fermentation of alcohols and carbohydrates. Miscellaneous fermentations (fat-splitting enzymes, oxydases, clotting enzymes) come in natural sequence. The chemistry of the albumins, the nitrogen cycle, and the sulphur cycle complete the fascinating story. Finally, practical applications are considered in the remaining chapters dealing with the fermentations of indigo, tea, cocoa, coffee, and the bio-chemical processes concerned in the purification of water and of sewage effluents.

It is hard to keep pace with the many attractive departments of scientific advance which are so active on all sides at the present day, but the man who wants to be sound in his rudiments on a given subject, without being forced to read a long account of researches which have founded principles will be grateful for a text-book which presents the story clearly and shortly and in the simplest terms. This is true of Dr. Fowler's excellent book, and the individual who is anxious to know what the simple cell is and does, what ferments, nzymes, and oxydases are, and how they serve practical, purposes, will find the help he needs in this volume.

Diagnostic Therapeutics: a Guide for Practitioners in Diagnosis by Aid of Drugs and Methods other than Drug-giving. By ALBERT ABRAMS, A.M., M.D. (Heidelberg), Consulting Physician to Mount Zion Hospital and the French Hospital, San Francisco; formerly Professor of Pathology and Director of the Medical Clinic, Cooper Medical College. With 198 illustrations. London: Rebman, Limited. 1910. Pp. 1039. Price 21*s.*

THE somewhat cryptic title of this book gives but little clue to the nature of its contents and small justification for its size. In the preface we are informed that it is a work neither on therapeutics nor on diagnosis, but that an attempt has been made to coördinate both subjects with a special object in view. The nature of that special object is, however, left nebulous, and in substance this book seems to us to be a very lengthy and discursive expression of the author's views on the actions and uses of drugs and other therapeutic measures. Diagnosis by the results of treatment is at best a confession of inability to establish the nature of the condition of a patient on a sound rational basis, and the success of a given drug or measure cannot be regarded as confirming a tentative diagnosis. As our knowledge of disease processes and their effects increases, the rôle of diagnostic therapeutics, if we may adopt Dr. Abrams's nomenclature for the moment, should contract more and more, and even now we cannot but feel that its scope is limited. At the same time, in justice to Dr. Abrams, it is only fair to mention that his book contains a great deal of useful information, the outcome obviously of a wide experience of practical medicine.

The first chapter is given up to some general observations upon diagnosis and treatment, and bears little relation to the subject to which the book is ostensibly devoted. The second chapter deals first with the interfering action of drugs in diagnosis, which includes a discussion of the difficulties introduced by injudicious medication in obscuring some symptoms and inducing others, such as drug eruptions. Drugs in the etiology of disease are next considered, and under this heading the toxic effects of various medicinal agents and their special effects in susceptible persons are described in some detail, the various drugs being dealt with in alphabetical order. Drug diseases are then tabulated according to the effects produced by the drugs. Food in the etiology of disease forms the next subject discussed. Questions of diet, of food poisoning, of metabolic diseases, of intestinal and other parasites, and of constitutional diseases caused or modified by diet, are reviewed in this

section. This chapter concludes with a study of methods other than drug-giving in the diagnosis of disease. Various processes, such as blood-letting, catheterisation, lavage, exploratory punctures, and the use of the X rays, are described in full, together with the accidents which may occur from their use.

The subject of the third chapter is, according to its heading, that of drugs in diagnosis, or diagnostic pharmacotherapy. It is here that one might expect some justification for the title of the book, and certainly the indications in regard to diagnosis afforded by the administration of drugs are incidentally discussed, but the 222 pages to which this chapter extends are more concerned with the therapeutic uses and effects of the drugs than with their employment for diagnostic purposes. The fourth chapter, which is even longer, deals with methods other than drug-giving in the diagnosis of disease, and includes detailed descriptions of most of the mechanical methods of treatment and diagnosis as well as of psychotherapy. The fifth chapter is headed Diagnostic-etiologic Therapeutics, and is concerned with questions of the previous diseases of patients, diatheses, and conditions associated with special periods, such as childhood, puberty, pregnancy, lactation, and senility. The sixth chapter is even less related to the subject of diagnostic therapeutics, since it is concerned with the diagnosis of visceral sufficiency. We can imagine a smaller book strictly devoted to the consideration of the so-called therapeutic test in diagnosis being both interesting and useful, but Dr. Abrams, by his discursive, anecdotal, and allusive style, has defeated the object he presumably had in view.

Military Sanitation and Hygiene. By E. BLAKE KNOX, B.A., M.D. Dub., D.P.H. R C P.S. Irel. (Hons.), Captain R A M C. With 21 illustrations. London: Baillière, Tindall, and Cox. 1911. Pp. 346. Price 5*s.* net.

THIS is an excellent manual dealing with the subject of military sanitation and hygiene from the point of view of those whose duty it is to assist in keeping all ranks fit for the supreme test—namely, the test of war. There are succinctly laid down in it all the essential matters dealing with the medical inspection of troops in barracks, the environment of the soldier as regards the points connected with his barracks, with the disposal of excreta and sewage, the sanitation in camp and bivouac, the conservancy for encampments, the water-supply of camps in peace and war, the food of the soldier, questions connected with clothing and equipment, and the points in relation to marching. In addition there is a chapter especially devoted to physical efficiency, the subject being discussed under the heads of personal hygiene, cigarette smoking, and physical training. Here nothing seems to have escaped the notice of the author; we are glad to see he lays stress on the necessity of greater attention to the soldier's teeth, thus obviating many of the barrack-room affections, such as sore-throat and chronic tonsillitis, leading to deafness. Doubtless many digestive affections owe their origin to, or are aggravated by, imperfect mastication due to bad teeth. The last chapter is devoted to the collection of sanitary intelligence. Here we would especially draw attention to remarks on the food of the soldier considered in all its aspects—the soldiers' rations during peace, questions concerning the inspection of fresh meat, the diseases affecting meat, the soldiers' rations during war, the matters relating to preserved food, all of which are comprehensively yet concisely considered.

In these days, when company officers have to teach their men elementary sanitation, such a work as the present, together with the excellent manual of Lieutenant-Colonel R. Firth on Military Sanitation, will supply all the necessary information. Medical officers cannot carry large tomes about with them on service or in camps of exercise; but in the volume under review they will find nothing omitted of importance on the subjects of which the author treats. We heartily congratulate the author.

Les Arythmies. (*The Arrhythmias.*) Par Le Docteur H. VAQUEZ, Professeur Agrégé à la Faculté de Médecine de Paris, Médecin de l'Hôpital Saint-Antoine. Leçons recueillies par le Docteur CH ESMEIN, Chef de Clinique adjoint à la Faculté de Médecine de Paris. Avec 48 figures dans le texte. Paris: Librairie J. B. Baillière et Fils. 1911. Pp. 437. Price 15 francs.

UNTIL recently conditions of cardiac irregularity received but scant attention, and our knowledge in regard to their origin and significance was extremely slight. The more careful investigation of these cases by graphic methods and the study of the fundamental properties of heart muscle in relation to disturbance of the rhythm of the heart's contractions, have invested the subject with a real practical interest, and have already afforded much useful information. In the book before us Professor Vaquez has supplied an instructive, readable, and interesting account of the present state of our knowledge in regard to this subject. The lectures upon which this book is based have been reported and edited by Dr. Esmein in such a way that the subject-matter retains the didactic and simple form in which it was obviously delivered, which renders it easy to grasp and to follow.

In the earlier lectures a brief history is given of the study of arrhythmia, and a careful discussion of the myogenic and neurogenic theories of the inception of the cardiac rhythm is included. The importance of the primitive cardiac tube and of its remains in the adult organ in the form of the bundle of His, and the nodes of Tawara and Keith and Flack, is clearly brought out. An interesting summary of the fundamental properties of heart muscle and of the relation of these properties to arrhythmia is also given. The various graphic methods employed in the investigation of disturbances of the heart's rhythm are described and illustrated by photographs and reproductions of tracings. An apparatus for recording the movements of the left auricle by means of a tube passed down the œsophagus is described, and the interpretation and value of tracings obtained by it are carefully considered. A clear account is given also of the recording of electrocardiograms by means of the Einthoven string galvanometer. Professor Vaquez is careful in the description of any graphic method to discuss fully its limitations and fallacies.

After these preliminary questions have been dealt with he proceeds to discuss the classification of the various forms of arrhythmia, and adopts as most satisfactory those proposed by Dr. James Mackenzie and by Professor Hering, which are in effect almost identical. The subjective sensations associated with different forms of arrhythmia and their significance are clearly considered in a separate chapter. The individual forms of cardiac irregularity are then dealt with categorically, those first analysed being the physiological modifications associated with the phases of respiration and with the change from the recumbent to the erect position. The characters of extra-systoles, their mode of origin, varieties, and prognostic significance are next studied in great detail. An exhaustive examination of the clinical characters of paroxysmal tachycardia is given, and the results of recent work upon its pathogeny are critically considered. Professor Vaquez regards this condition as an accumulation of extra-systoles, and he refers it to a modification of the excitability of the heart muscle, analogous to that which leads to the occurrence of the ordinary forms of extra-systole. The nervous system is described as having only an indirect effect in its production. Both paroxysmal tachycardia and extra-systoles are said to be

favoured by a pre-existing affection of the cardiac muscle. The characters of the pulsus alternans, of the persistent irregularity described as perpetual arrhythmia, or pulsus irregularis perpetuus, are next fully described, and the various views current as to their production are presented clearly and are critically discussed. An interesting chapter is devoted to the consideration of the prognosis and treatment of the arrhythmias.

A well-arranged bibliography and a useful index add to the value of this work, which we can cordially recommend to our readers as affording an impartial account of the present state of our knowledge in regard to the subject with which it deals, and an interesting presentation of the advances which the graphic method of studying the circulation has afforded. It is gratifying to notice that ample justice is done to the work of English and American investigators, particularly to that of Dr. James Mackenzie, whose pioneer work on this subject is quoted in connexion with every form of arrhythmia.

LIBRARY TABLE.

The Individual and Society; or, Psychology and Sociology. By JAMES MARK BALDWIN, D.Sc., LL.D., Professor in the National University of Mexico. London: Rebman, Limited. 1911. Pp. 210. Price 6*s.* 6*d.* net.—This little book was, we learn from the preface, written under "very exact and exacting limitations of space imposed by the editor of the series"—i.e., the French Bibliothèque Internationale de Sociologie. It is, therefore, necessarily somewhat superficial. Professor Baldwin's text is, to use his own words, as follows: "Society is looked upon as a mode of organisation *sui generis*, its matter is psychological; its rules of organisation are those which characterise the personal development of minds in relation to one another. ..... Sociology itself, dealing with the external and historical aspects of social life, must allow and demand the psychological interpretation of its results." Professor Baldwin reminds us that "the social relation is in all cases *intrinsic to the life, interests, and purposes of the individual;* he feels and apprehends the vitality of social relations in all the situations of his life"—a saying which we take to be the modern translation of Aristotle's remark, φύσει πολιτικὸς ἄνθρωπος. Sociological study, Professor Baldwin says, must be informed and renewed by a psychological interpretation of the facts. From our own particular point of view the most interesting portion of the book is that in which (p. 169 *et seq.*) Professor Baldwin discusses the problem of the sterilisation of the unfit, and he has no doubt that with the progress of medical and surgical science and the corresponding recognition of this social need "eugenic progress will be in this direction." But the problems stated in the book are so wide and far reaching that we cannot think that the work can be considered of much value in itself, except in so far as it may lead the reader to consult Professor Baldwin's larger works upon similar subjects.

A Short History of Bond street, Old and New. From the Reign of King James II. to the Coronation of King George V. By H. B. WHEATLEY, F.S.A.. Also Lists of the Inhabitants in 1811, 1840, and 1911, and Account of the Coronation Decorations, 1911. Published for the Bond-streets Coronation Decoration Committee by the Fine Art Society, 148, New Bond-street. 1911. Pp. 36. Price 2*s.*—Old Bond-street was built in 1686, New Bond-street, as far as Clifford-street, soon after 1700, and the extension to Oxford-street was commenced somewhere about 1721, so that the most aristocratic street of shops in London has had about two centuries of life in which to develop from a residential into a business thoroughfare, always preserving its reputation as a haunt of the fashionable world. The committee which was responsible for its uniform and distinctive decoration on the occasion of King George's coronation has done well in having had compiled by so sound an authority as Mr. Wheatley a succinct history of Bond-street's development from the days when Sir Thomas Bond, formerly a devoted follower of Charles II. in exile, headed the syndicate of adventurers who developed a portion of the estate on which Clarendon, in the last days of his prosperity, had erected the mansion destined to look down for so brief a period from its superior elevation upon St. James's Palace. Bond-street in its early days ran through fields, as Kip's old print of Burlington House, reproduced in Mr. Wheatley's book, plainly shows; and, indeed, he tells us how the great Sydenham, living, after a varied career, in Pall Mall (where he died in 1689), was robbed of a silver cup by a house-breaker, and how the thief was lost to pursuit in the bushes about the Conduit Mead. Bond-street hardly seems to have been a medical street in the nineteenth century. Of earlier days no lists appear to be available, although Mr. Wheatley reminds us that Fielding, in "Amelia," sends Colonel Bath to the house of an eminent surgeon in Bond-street to have his wounds dressed. In the lists republished by the author, George Spence, dentist to the King, is recorded to have been living in 1811 at No. 17, and P. Elizee, surgeon, at No. 36, Old Bond-street; and in 1840 "Smyth, Surgeon," is assigned as the tenant at No. 41, Old Bond-street, "Dr. Culverwell's Bathing Establishment" being at 23, New Bond-street. Among the celebrated names associated with the street's past history and reproduced in its recent decorations two may be mentioned from Mr. Wheatley's record. Laurence Sterne died in 1768 at No. 41, Old Bond-street, in the presence of a nurse and John Macdonald, a footman, sent to inquire after his health, who records, "I went into the room and he was just a-dying. I waited ten minutes, but in five he said 'Now it is come.' He put up his hand as if to stop a blow and died in a minute," a dramatically terse and restrained account of such a scene. The second is Bond-street's most distinguished inhabitant, Nelson, who about 1797 lived, we believe, at No. 147, now occupied by Mr. Charles Davis, the well-known dealer in antiques. Nelson lay there for three months wounded and suffering after the loss of his arm, tended by Lady Nelson and obtaining rest only by the use of laudanum. In the next century, after his death, Lady Hamilton lived at a house then numbered 130, and Mr. Savory, of Messrs. Savory and Moore, is mentioned by Mr. Wheatley as the possessor of a silver cup, her gift to his great-uncle, in return for services rendered by him as an apothecary. The name of the firm occurs at their present address in the list of 1840 already referred to, but that of 1811, being that of a "Town Visiting Directory," does not give it. Their beautiful old shop front, one of the few surviving in this part of London, is the subject of an illustration. The booklet is a readable one and might well be imitated in respect of other thoroughfares in our ever-changing metropolis.

Public Health and National Insurance. By H. MEREDITH RICHARDS, M.D. Lond., Medical Officer of Health and School Medical Officer, Croydon. London: P. S. King and Son. 1911. Pp. 77. Price 6*d.* net.—The greater part of this pamphlet consists of articles that have already appeared in several journals, including THE LANCET. As the medical officer of health of a large borough, a school medical officer, a medical referee to a large corporation, and an ex-police surgeon, the author may claim a wide experience in the conditions that render the National Insurance Bill such a complex problem. Those, he says, engaged in preventive medicine feel that a great opportunity will have been lost if the Bill simply results in stereotyping club practice. As to the various proposed

methods of payment, the author considers that no one method is to be preferred in all circumstances. He suggests that the Insurance Medical Service should be organised on preventive lines, and that both this and the existing public health service should be placed under a committee on which the insured, the medical profession, and the ratepayers should be suitably represented. He sketches out a plan under which a Statutory Health Committee, constituted as above described, should establish clinics staffed by part-time or whole-time salaried medical officers, to treat patients referred to the clinics, act as consultants and referees in respect of unusual claims, and undertake the medical work now devolving on the borough and county councils, such as school inspection. The committee should also arrange with general practitioners for attendance on the insured. The author further discusses the sanatorium benefit and the relation between the Bill and public health. In an appendix four main types of sick and medical benefit clubs are illustrated by concrete examples: the ordinary friendly society, the deposit society, the slate or dividing society, and the works club. The author insists that the system of insurance will not achieve its great possibilities of utility if it fails to correlate the medical service of the insured with the existing public health and educational services, or if it denies equitable payment for public work.

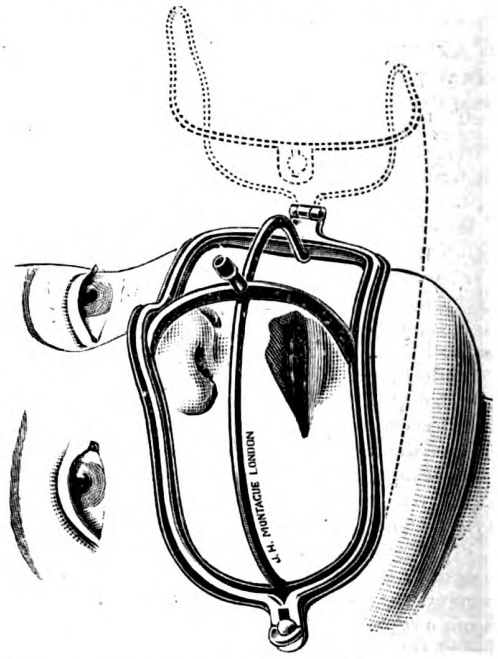
Retrospective Memoranda. By Sir JONATHAN HUTCHINSON, F.R.S. Subject Index and Index of Names, compiled by CHARLES R. HEWITT, Librarian to the Royal Society of Medicine. (New Sydenham Society's Publications.) London: H. K. Lewis. 1911. Pp. 70.—This is a memorial volume containing a short account of the New Sydenham Society, which, originating in 1859 on the death of the original Sydenham Society, was wound up in 1907. The book contains, also, an index catalogue of the society's publications and of the authors and translators of the works published by it, also portraits of Sir Jonathan Hutchinson and the late Mr. Henry Power. In the concluding words of his Memoranda Sir Jonathan Hutchinson says: "I do not believe that either of the two societies—the Sydenham or the New Sydenham, or both—have exhausted their field of productive labour. It may, perhaps, in each instance, have been for the best that its special organisation came to an end when it did, but there is surely no good reason why a third generation should not suitably engage in similar work." But he gives some sage advice to any who may be tempted to follow in this line—viz., not to undertake any large books, lexicons, year books, large-paged atlases, or works involving original composition or associated work, and, above all, nothing that cannot be finished promptly. It is interesting to note that the surplus sum of £171 10*s.* 8*d.* remaining after the discharge of the society's liabilities at its winding up was presented to the library of the Royal Society of Medicine for the purchase of works of special value to be marked as the gift of the New Sydenham Society.

The Dental Directory, 1911. London: John Bale, Sons, and Danielsson, Limited. Pp. 200. Price 2*s.* 6*d.*—This directory contains the names and addresses of registered dental practitioners, arranged both alphabetically and topographically, together with the date of their qualification and hospitals and places of medical education, practising in the United Kingdom, the Channel Islands, the Isle of Man, the colonies, and abroad. Information with regard to the dental hospitals and schools in the United Kingdom, dental societies, and dental publications is also included, with other useful information. As it does not seem to be generally known that the Channel Islands and the Isle of Man have special Dental Acts of their own, this fact is referred to by the publishers in a prefatory note. The book is of the convenient size of 8 in. by 3½ in.

New Inventions.

A NEW FRAME FOR THE ADMINISTRATION OF CHLOROFORM AND ETHER BY THE OPEN METHOD.

THE frame figured differs essentially from those generally in use in that its long axis is at right angles instead of parallel to that of the face. The frame (roughly the shape of a Napoleon hat) consists of a narrow trough adapted to the transverse curves of the chin and cheeks, and having a deep indentation to accommodate the nose. On this base is built up a framework of two metal arcs joining the respective extremities of the long and short axis of the bed frame, that joining the extremities of the short axis being a tube perforated on its under side, and having an extension at its highest point for the attachment of a Junker or oxygen tube (as in other patterns). The lint covering is kept firmly in position by a wire frame closely fitting the bed-frame and hinged to it at one end. The advantages



claimed for this frame are: 1. That it is more convenient to use, having but little tendency to slip off the face, and also having one of its poles close to the hand which controls the angle of the jaw. 2 That it fits the face more accurately than other patterns, and allows of the entry of less vapour-free air in patients with moustache and beard—a point of especial importance in the open administration of ether. 3. That it is convenient for operations on the upper part of the face, as a space of a full inch can be obtained between the upper edge of the frame and the lower border of the orbits. The narrow metal trough, though not peculiar to this apparatus, minimises the risk of chloroform burn without making the frame clumsy.

The frame has been made for me by Mr. J. H. Montague, of 69, New Bond-street, London, W.

South Kensington, S.W. E. V. DUNKLEY, M.D. Lond.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—At the annual general meeting of this society held on July 14th the following officers for 1911–12 were elected:—President: Mr. W. McAdam Eccles. Treasurer: Mr. T. Gunton Alderton. Secretaries: Mr. D. F. Maunsell and Mr. N. Bishop Harman. Librarian: Dr. Arthur Saunders. Editor of Journal: Mr. H. W. Chambers. Editorial secretary: Mr. Aslett Baldwin.

THE LANCET.

LONDON: SATURDAY, JULY 29, 1911.

The British Medical Association: the Presidential Address.

THE Presidential Address of Professor ROBERT SAUNDBY, delivered at the opening of the Seventy-ninth Annual Meeting of the British Medical Association, will be found on another page. It contains so much that is of interest and value in connexion with the National Insurance Bill, and with the position occupied by the medical profession in the discussions arising thereon, that it is unfortunate that it probably will not be as widely read as it deserves to be by those laymen whose full appreciation of the points at issue is to be desired. For it is particularly important, not now but always, that the public should be able to understand the medical view. The question of the position which the medical profession should occupy under the new legislation is a matter of vital and intrinsic importance to that profession, and of no less vital and intrinsic importance to the public; and we are glad to observe that the feeling is growing among the public that, so long as the members of the profession seek to insist upon a right to be a party to a bargain, justice must uphold their view. A bargain honourable to the profession and beneficial to the community is what we want, and not to have obligations thrust upon us by the legislature and our status altered in the economy of the nation despite our just and reasoned disapproval. The position of the medical profession at the present critical moment is one calculated to add weight to its claims for due consideration. Its recent progress may be traced by anyone who studies, and is able also to read between the lines of, the opening of Professor SAUNDBY'S address. The advance made in medical education, which he illustrates from presidential addresses delivered in past years at Birmingham, is a great and notable fact which few are likely to ignore or to deny if it be brought to their memories. The widening of the aims of medical science, and the prominence which it has given to the prevention, as distinct from the healing of disease, have a similar bearing upon the controversies connected with the National Insurance Bill. For the progress of medical science and the development of medical education have supplied the motive for the introduction of a measure which would have had no *raison d'être*, so far as its medical clauses are concerned, if the possibilities of medical beneficence had not been such as to command universal recognition. Those possibilities are the result of the work done by the medical profession in the past; and our students are being trained not merely to equal but to excel the achievements of their predecessors. Upon those grounds, if upon no others, the medical profession should have an irresistible claim to the right to be consulted, in order that the work which it is to have assigned to it in the future may be conducted with the fullest possible measure of efficiency.

The two principal points in the discussion of national insurance to which Professor SAUNDBY refers in that part of his address which deals directly with the imminent Bill are naturally the methods of control of the administration of medical benefits and the system of payment of medical men to be adopted. With regard to both matters the medical profession speaks from experience and from observation, and not speculatively, but in the first place it insists upon its right to be heard (using the expression we have employed above) as a party to a bargain, and not as a subservient body upon which an obligation may be imposed without its consent. The individual who undertakes service for the State knows, when he does so, to whose orders he will be subjected, and his confidence in the competence of that authority is one of the inducements for him to serve. He knows, that is to say, the class to which those in authority over him will belong, and the degree of fitness which is likely to characterise them. He may volunteer to perform a particular act subject to leadership of a totally different class, but he cannot with fairness be obliged to do so. The medical man who has entered upon his profession has not submitted himself to authority at all other than that governing the profession of which he has become a member, and the Bill proposes to limit his professional sources of income, or possibly to annihilate them unless he will allow himself to be controlled by bodies which he has had under his observation and whose control he looks on with mistrust. Professor SAUNDBY will be found not to confine himself to criticism of the Friendly Societies, but to supply pertinent and relevant facts with regard to the conditions which have prevailed in Germany, where the administration of medical benefits has been placed in the hands of committees managed by working men. A trades union, having recourse to strikes in order to enforce the rights of its members, has been, briefly, the only means open to the German medical men concerned in order to protect themselves against intolerable conditions of practice. Surely it would be better to have the fullest discussion beforehand, and the consent of the profession at large to the innovations proposed, than to go forward too quickly, and so drive an outraged profession to the methods of the dock labourer, with the difference that in the case of the dock labourer his cessation from the performance of his duties does not involve the risk of human lives.

With regard to the method of payment for the service to be rendered, we are shown the example of what has occurred elsewhere in the instance cited by Professor SAUNDBY from Switzerland, where the result of the allotment of fixed salaries to medical practitioners was found to be that the demands of the public for professional attendance by night and by day could not be satisfied, so that the practitioners had to abandon an arrangement into which they had more or less voluntarily entered. From the other point of view—that of the public, whose interests are at stake as essentially as those of the medical profession—Professor SAUNDBY rightly points out that "the services of a medical practitioner are above all others difficult to appraise, but no one can doubt that they cannot be adequately rendered if he is unable to spare the necessary time to

examine his cases. What can be the good of spending millions on the provision of sanatoriums for phthisis if the medical attendance is to be of such a character that early cases will rarely be recognised? The interests of the public are at one with those of the medical profession in the need for putting an end to contract work." The truth of the matter is that the aim of the National Insurance Bill, and of the Chancellor of the Exchequer in introducing it, is not that of the Friendly Societies, who in providing medical attendance in accordance with their own estimate of the value of medical science have brought into existence most of the evils of contract practice. Mr. LLOYD GEORGE has the ambition to give the people at large not the benefits of medical attendance already secured voluntarily for themselves by the members of Friendly Societies, but a great deal more. The Friendly Societies have been content, as a rule, to provide their members with such a semblance of medical attendance as may be rendered by an underpaid medical officer who, if he is to earn a decent livelihood, must reduce the time expended upon many of his cases to a very undesirable minimum. Mr. LLOYD GEORGE aims at obtaining for the working classes of the country the full benefits of modern medical science and the services of those who have taken best advantage of modern medical training. His difficulty is to do this with the financial means at his disposal, and the solution of the problem can only be found by securing the effective goodwill of the medical profession, who are in accord with his aims, as we have just stated them, but who differ from him as to the means by which these may best be attained, and as to the extent to which the attempt to attain them should be made at their expense. Professor SAUNDBY makes out a good case for delay in passing the National Insurance Bill until the medical profession has been adequately consulted—one of the two main points for which we have striven in THE LANCET. Our other contention could not be put in better words than those which he has employed, where he states that in the public interest contract medical work should be abolished.

The Coöperation of Medicine and the Public in the Campaign against Tuberculosis.

IN discussing Professor SAUNDBY'S wise and moderate address, delivered before the British Medical Association on Tuesday last in his Presidential capacity, we lay stress on the national benefits that must ensue from a better understanding by the public of professional aims and hopes. Such a conference, briefly reported elsewhere, as that which was held last week in London by the National Association for the Prevention of Consumption and other Forms of Tuberculosis forms a very good example of what we mean. Administrative action in regard to matters of public health, if it is to be effective, requires a preliminary education of public opinion as a necessary antecedent. A great deal of useful educational work with this object in view has been carried out in regard to tuberculous diseases by members of the medical profession, public health authorities, philanthropic agencies, and individuals. The most healthy sign of the awakening of the public interest in regard to these matters is the attention which is now being given by statesmen and municipal authorities to them. The practical measures which are being organised to deal with tuberculosis are probably to be regarded as the outcome of the fact that everyone now knows that consumption, the commonest form of tuberculous disease, is communicable through the agency of dried sputum from cases of this disease. That one result of this knowledge is a tendency to shun the unfortunate sufferer from this disease is a regrettable though intelligible fact. If it can be still further brought home to the public generally that the disease is in a very large majority of cases curable if recognised early and appropriately treated, and that it is preventable and not an inevitable result of family predisposition, there can be little doubt that an effective and comprehensive campaign both curative and prophylactic will soon be inaugurated. There are not wanting encouraging indications that some such effective mechanism may shortly be evolved. The recent Order of the Local Government Board in regard to the notification of patients suffering from pulmonary tuberculosis is one step forward. The publication of the final report of the Royal Commission on Tuberculosis (Animal and Human) has drawn attention in no uncertain manner to the dangers of milk from tuberculous cows, even in the absence of tuberculous disease of the udders. There are reasons for hoping that before very long this will result in the enactment of measures to secure a purified milk-supply. Again, the proposals in the National Insurance Bill now before Parliament to devote a large capital sum and an annual contribution to the erection and maintenance of sanatoriums are striking evidence of the recognition of the importance of this disease in regard to the industrial population. The prominence which is now given by the lay press to these questions, the establishment of dispensaries, the educational and nursing work carried out by health visitors and trained nurses are all useful agencies in the campaign, and afford further indications of public interest in it.

It will be seen that the annual conference of the National Association for the Prevention of Consumption and other Forms of Tuberculosis came at an opportune moment, and it was certain that it would secure for its deliberations and recommendations considerable public notice. Not a few of the speakers emphasised the importance of the diffusion of knowledge in regard to tuberculosis. Mr. JOHN BURNS, in a forcible and practical opening address, stated that the "man in the street" was now determined to coöperate with the medical officer of health, the town and county council, and the private practitioner in the important work of the campaign against tuberculosis. He gave statistics in regard to the death-rate from tuberculosis, which showed how marked was the decline of the disease during the last 50 years. He pointed out the significance of the fact that the diminished incidence of consumption was concurrent with increasing sobriety, better housing, growing education, and the social and moral elevation of the people. Professor SIMS WOODHEAD, in advocating the

inclusion of hygiene in the curriculum of secondary schools, as well as in elementary schools, maintained that the education of the public by means of exhibitions and lectures and other methods was one of the most important developments of modern hygiene and medicine. Dr. F. C. SHRUBSALL stated that the Education Committee of the London County Council had decided to provide a course of lectures for teachers on the manner in which they could assist the anti-tuberculosis campaign. Sir WILLIAM OSLER believed that the public were now alive to the necessity for dealing with this insidious disease in its early stages. He reviewed the various methods of treatment, and maintained that since not more than 10 per cent. of the cases could be treated in sanatoriums, our energies should be directed very largely to the elaboration of the successful home treatment of the disease. Among other important subjects discussed at the Conference were the value of sanatorium treatment, the educative value of sanatoriums, after-care, schools for tuberculous children, and the segregation of advanced cases. All of these matters are of such real importance in regard to the treatment and prevention of the disease that it is to be hoped that the reports in the lay press will be widely read. They were in many journals so full and good as to relieve us of the responsibility of more than indicating the views of the various speakers.

The proceedings of the Conference show how many and varied are the agencies which are being employed in the campaign against tuberculosis. What is now needed is the coördination and extension of these agencies together with the necessary financial assistance to enable them to be effectively employed. In matters concerning the public health, where costly financial questions are concerned and where certain official interference with the personal liberties and conditions of the patient is involved, such as notification and possible segregation, Parliamentary action can hardly move in advance of public opinion. Indeed, it is liable in some instances to be deferred until public pressure enforces it. It is obvious, therefore, that the coöperation of the public with the medical profession in this campaign is the essential factor necessary for its success. Both Mr. JOHN BURNS and Mr. WALDORF ASTOR pointed out the economy that would be effected in regard to the expenses of the Poor-law, and in disablement benefits, if the disease could be stamped out or even satisfactorily dealt with. There can be no doubt that the immediate outlay involved would soon be compensated by the better health of the community, and we hope that the pressure of public opinion will accelerate the achievement which the medical profession have so constantly in view.

The Medical Officer of the London County Council.

THE announcement that Sir SHIRLEY F. MURPHY will vacate his post as chief medical officer of health to the London County Council at the end of the present year, which was made at the meeting of the Council on Tuesday last, will be received with universal regret. Men occupied in every variety of medical inquiry have long become accustomed to rely upon the central medical department of the metropolis for information as to the prevalence and prevention of disease and for guidance on every variety of administrative question relating to public health in London. Many will find it difficult to realise that it is hardly more than 20 years since the department was created, and that before that time there was no authority charged with the care of the public health of London as a whole. Sir SHIRLEY MURPHY, the first medical officer of health of the London County Council, was appointed when that body came into existence in 1889, and his well-known series of annual reports began in 1892. The period which has since elapsed has been eventful in the sanitary history of London. Large political changes have been made in the units of administration, and a mass of special legislation has been enacted at the instance of the Council in which sanitary reforms have had to be adapted to the complicated system under which the metropolis is governed. New matters in abundance have been brought within the province of public health administration, while older problems have needed reviewing and developing as epidemiological knowledge has increased and methods of prevention have improved. In all such questions it has been of first importance that the London County Council should have expert advice of the highest order and obtain from its medical officer of health a balanced judgment and continuity of policy. It is only necessary to consider how a great elective administrative body may be divided by conflicting interests, urged by enthusiasts or "anti-" organisations or restrained by reactionaries, to realise the magnitude of the service which Sir SHIRLEY MURPHY has rendered in these respects. We do not attempt here to particularise the sanitary reforms of recent years—for example, the housing of the poor, the organisation of the control over infectious diseases, or the better supervision of milk and food supplies—which have so largely been due to Sir SHIRLEY MURPHY'S initiative or guidance. A catalogue of these would fill many columns; it is sufficient to say that to-day the sum of all his activities is a healthier London; no greater commendation could be given.

The report presented by the General Purposes Committee and adopted by the Council on Tuesday contained a striking testimony to the worth of Sir SHIRLEY MURPHY'S services. The committee's report was also memorable in another respect. It recommended a new policy, which has now been accepted by the Council, for placing the whole educational medical service, as well as the general work of the public health department, under the control of the medical officer of health of the county, who will thus in future be directly and primarily responsible for administration of both branches, and for the advice given to the Council in matters relating to the medical examination and after-treatment of school children, as well as in other subjects. Readers of THE LANCET will not need to be reminded of the prolonged controversy which is terminated, we hope finally, by this important decision. Hitherto, the association of the county medical officer of health with the direction of the medical work of the Education Committee of the Council has at best been merely nominal; it may be said that in practice there have been two medical services—one under the county medical officer of health, the other under the medical officer (education). The failure which has notoriously occurred in the

organisation of the inspection of London school children and the arrangements in connexion with "after-treatment" must in large measure be ascribed to the repeated neglect of the Council in the past to utilise the great administrative experience which could have been made available had the medical service been consolidated under the county officer. When the failure had to be acknowledged, and a new organisation became imperative to meet the demands of the Board of Education, the Education Committee of the London County Council proposed a still more retrograde policy, which would have resulted in the care of the health of the school children of London being divorced from that of the rest of the population and handed over to the lay head officer of the Education Department, to whom the medical officer (education) would have been responsible. In emphasising the obvious objections to this policy in our issue of Feb. 25th we ventured to prophesy that it could not be maintained, and that the alternative of amalgamation of the medical services under one medical head must soon be accepted. The decision to which the Council has now come will, we believe, be welcomed by all who have the best interests of the public health service at heart, and who have viewed with dismay recent tendencies to regard the school child as an article strictly preserved for subjection to "educational" authority, even in such matters as the prevention and treatment of disease. It is greatly to be regretted that the large reorganisation which will now be necessary is not to be undertaken by Sir SHIRLEY MURPHY himself. But obviously the task is one which will require sustained and continuous work for many years, and the rules for compulsory retirement on the attainment of the age limit are strictly guarded and enforced. The Council, however, "so that his successor shall have the advantage of his long experience, particularly in the details of medical administration," have wisely made special arrangements to retain Sir SHIRLEY MURPHY'S services in a consultative capacity.

Annotations.

"Ne quid nimis."

SUPERANNUATION FOR MEDICAL OFFICERS OF HEALTH.

A BILL to provide for the superannuation of medical officers of health in England and Wales was introduced into the House of Commons on July 20th by Dr. A. P. Hillier, supported by Sir Clement Hill, Mr. John Robertson, Mr. Henry Forster, Colonel Hickman, and Mr. Barnes of the Labour party. All medical officers of health, whether devoting their whole time to the duties of their offices or not, are included in the provisions of the Bill, which is on a contributory basis. The scale of contributions is equal to 2, 2½, or 3 per cent. of each year's salary, according to whether the contributor has been five years, 15 years, or more than 15 years in office respectively. The superannuation allowances are the same as those provided by the Poor-law Officers' Superannuation Act, 1896, namely, one-sixtieth of the average salary of the final five years for each year of service, with this important addition, however, that after ten years' service an additional five years are added for the purpose of computing the allowance. Provision is made in the Bill for the return of the contributions under certain contingencies, and within three months of the commencement of the Act those medical officers of health whom it concerns may contract out. The superannuation allowances are to begin after the completion of an aggregate service of 35 years, or upon the attainment of 60 years, or after disablement sufficient to prevent the officer discharging his duties with efficiency. When an officer retires after serving more than one authority his superannuation allowance will be paid in suitable proportions by each of those authorities, thus avoiding the position created by the Poor-law Superannuation Act in which the whole of the allowance is paid by the authority whom the officer last served. Some of the metropolitan borough councils and a few authorities in the provinces have already made provision for the superannuation of their officials, and if the Local Government Board certifies that such provision is adequate these authorities will be exempt from the provisions of the Bill.

"THE PRIESTHOOD OF SCIENCE."

THE notion that schools of thought have at various times in the world's history deliberately falsified fact upon an established plan is one that fascinates a certain class of mind. In an extreme form this notion appears in the writings of the late Edwin Johnson, that almost insane doubter, who in his remarkable "Growth of English Culture" maintains the thesis that English history was the conscious invention of Benedictine monkish writers, who issued their fabrications at the time of the revival of letters, and that consequently half the time-honoured chroniclers, such as Gildas, Nennius, Bede, and Giraldus Cambrensis, are mystic persons, monastic deadheads, so to say, and the other half, such as Camden and Baker, are the dupes of the monks or myth-mongers. It is clear that if English history be a mere invention, then the history of English science and medicine is badly shaken, too. And not to confine ourselves to England, is it not possible that the School of Salernum is of the nature of myth? The idea that in the worlds of science and medicine people write to order and in obedience to a scheme laid down at some obscure and undesignated headquarters has for years obtained among a certain order of mind. We hear perpetually of the "Priesthood of Science," as though science were merely an affair of dogma and not of ordered fact, open to almost hourly revision. We hear, too, from those who in their heart of hearts do not like science, that it is "exploded"—that is the word—whenever such a revision has perforce to take place. We have heard an accomplished High Church Christian-Socialist clergyman maintaining before a completely ignorant and applauding audience that the queer Lenten mystery-play, *Everyman*—a dramatic performance at which it is customary for the audience to behave as though they were at a prayer meeting—has once for all unmasked science. It is amusing to think of Newton, Darwin, Lister, Tait, and Kelvin as bowled down by a crabbed miracle-play, chiefly concerned with the crudities of good and evil in the life of an individual in the Middle Ages. Darwinism was, of course, in the opinion of these credulous and would-be critical persons, "exploded" when Weismann came to the fore, and when Mendel was re-discovered by Professor Bateson and others. The young university man, untouched by scientific training and ways of thought, will maintain that Professor Bateson's writings prove that there is no sort of rule or law in descent. "You plant two peas," cries our eloquent young friend, completely dominating an applauding dinner-party audience, "and one of your peas

comes up six feet high and one is only above ground. And that's what Bateson says. And what becomes of your Darwin?" To verbal fireworks such as these the popular fallacy of "the Priesthood of Science" owes its inspiration. It is not, indeed, probable that at any time, even in ages of cynical obscurantism and ignorance, were men induced to form themselves deliberately into schools of deceit. It is almost to the credit of human nature that a lie is not consciously propagated. Man is too uninventive, and testimony is too scattered and independent, to admit of the consistent propagation of lies. This matter has been acutely discussed by Professor Haddon in his admirable little "History of Anthropology" recently published. But if planned mendacity of a whole school is an impossibility, we admit that in certain given surroundings, by means of traditional influences or through the compiler's indolent habit of copying down whatever he finds written by a previous scribe, many fallacies have enjoyed a vast vogue. Thus, in the age when phlebotomy was paramount in medical practice, medical writers undoubtedly propagated the fallacy of excessive bleeding by dint of copying its praises out of previous text-books. The public were impressed by the fact that all medical writers were in favour of a course of which the wisdom was later shown to be doubtful. Here, when the wisdom of blood-letting was impugned there arose, quite naturally, the idea of a medical conspiracy (a "Priesthood of Science," as men now name it), and such ideas, again, were the ancestors of the modern *cliché*, which represents science as a fallible and obscurantist conspiracy, at any moment liable to explosion.

THE PREVALENCE OF INTESTINAL WORM-INFECTIONS AND THEIR EFFECTS ON HEALTH.

THE frequency with which the natives of the tropics suffer from intestinal parasites, and the debilitating influences which such infections have upon the health of those engaged in industrial labour, make the subject one of much importance both from the medical and the economic point of view. Any investigation which helps to throw light on the causation or prevention of intestinal parasitism must be welcomed not only by the members of our profession who practise in tropical countries, but also by the employers of native labour in those regions. Among other places where such investigations have been carefully carried out we may mention the Philippine Islands, where the American experts attached to the Bureau of Science have done much good work in this direction. The latest of these contributions is published in a recent number of the *Philippine Journal of Science*, to which Dr. David G. Willets furnishes a paper entitled "A Statistical Study of Intestinal Parasites in the Tobacco Hasciendas of the Cagayan Valley," which he had read early in the present year at a meeting of the Manila Medical Society. It appears that this inquiry was undertaken by Dr. Willets with a view to determine the frequency and medical significance of intestinal parasitism in certain parts of the Island of Luzon, with particular reference to the incidence and significance of hookworm infections. The area selected for the investigation was one in which the native population was engaged almost entirely in the cultivation of the tobacco-plant. The fæces of 4278 workers were examined, and no fewer than 3656, or 85·46 per cent., of them were found to be infected by parasitic worms. It may be mentioned that the conditions under which the stools of the natives were examined were not favourable for finding the presence of amœbæ or flagellates, hence no systematic search was made for these two classes of organism, but it is believed that both of them are comparatively infrequent in the locality in question. Of the 4278 persons examined, 2038, or 47·64 per cent., had a single infection, usually either ascaris or ankylostoma; 1444, or 33·75 per cent., had a double infection, roundworms and hookworms being generally present together; 168, or 3·93 per cent., had a triple infection, mostly consisting of the two kinds of worm already mentioned, along with trichuris; while 6 persons, or 0·14 per cent., suffered from a quadruple infection. Ascaris was found in 2653 instances, or 62·04 per cent. of those examined; ankylostoma in 2326, or 54·37 per cent.; trichuris in 342, or 7·99 per cent.; while oxyuris was discovered in 64 instances, or 1·50 per cent.; and tænia in 59 cases, or 1·38 per cent. The other infections more rarely met with were hymenolepis, 5 cases; strongyloides, 4; and trematodes 1 instance. Ascaris was more frequent in females than males, but, on the other hand, ankylostoma was found more often in males than females; this may be accounted for by the fact that more males work in the fields, where presumably they contract the infection. As to the effects produced by these parasites on the health of the population, it is said that the people as a class are anæmic in appearance and apathetic in demeanour, conditions not infrequently met with in pronounced ankylostomiasis, as, for example, among the "poor whites" in certain of the Southern States of North America. Dr. Willets, however, is careful to point out that among the Filipinos on the Island of Luzon other local factors probably act in lowering their vitality. Among these, apart from the climate, may be mentioned too early marriages, and among the women too rapid child-bearing, poor quality of the food, excessive smoking of tobacco begun at a very early age, habitual indulgence in alcoholic drinks, also begun at an early age, and the prevalence of tuberculosis. It is unfortunate that the circumstances of the inquiry did not permit of a clinical study of each case and the collection of evidence as to definite injury, if any, to health inflicted by intestinal worms. Dr. Willets ventures the opinion that ankylostomiasis when uncomplicated by the presence of any other species of worm may be of less significance than cases in which two or more parasitic infections occur together in the same person. Much improvement in health is known to follow upon treatment which clears out all parasitic worms from the alimentary canal. We are informed on good authority that where worms are present in the intestine abrasions of the lining membrane are apt to occur, and that bacteria from the contents of the gut are liable to penetrate from these abrasions into the deeper tissues, giving rise to dangerous inflammations and septicæmias, or to perforation. At present the opinion seems to be that the chief influence of intestinal parasites is in lowering the vitality of the host and rendering him more susceptible to other diseases. Dr. Willets quotes the remarkable results which have been obtained in the Bilibid prison, Manila, subsequent to the inauguration of measures for securing systematic examination of the prisoners' fæces to detect the presence of parasites, followed by medical treatment when necessary. Before the supervision of the prison was taken over by the Bureau of Health (of which Dr. V. Heisser is now the distinguished director) the mortality of that institution had attained the appallingly high rate of 238 per 1000. After certain sanitary improvements had been carried out by the Bureau of Health the death-rate fell to 75 per 1000, below which it seemed impossible to reduce it. After the measures mentioned above for detecting intestinal parasites and for treament had been carried out, the mortality sank to the comparatively low rate of 13·5 per 1000. This decreased mortality was not at first general all over the prison, but was observed to follow, section by section, the application of the systematic treatment for intestinal parasites among the inmates. It cannot therefore be disputed that this dealing with worm

infections was largely instrumental in effecting a reduction in the death-rate of Bilibid prison. As regards the prevention of parasitic worm infections among the workers in the tobacco plantations of the island of Luzon, this, as elsewhere, seems largely to depend upon the provision of proper and sufficient privy accommodation for the people, so that indiscriminate defæcation, and consequent contamination of the surface of the soil by infected human excrement, may be avoided.

THE SANITARY COMMISSIONER WITH THE GOVERNMENT OF INDIA.

THE recent and sadly sudden death of Lieutenant-Colonel J. T. W. Leslie, C.I.E., I.M.S., Sanitary Commissioner with the Government of India, has been made the occasion of an appeal by the *Times of India* for the abolition of this high appointment on the grounds that it is an appointment which should never have been created. Our contemporary says:—

> It is a post which owed its existence to the wave of centralisation which afflicted the Government of India and fastened upon us unnecessary offices like the Inspector-General of Excise, for which there was not the slightest justification. It is an appointment which should never have been created. If it had been created it should have been filled by a practical sanitary officer, not by one with no special qualifications for the office. In effect it has been impossible to trace any advantage from the establishment of the post, and it set up no little friction between the Government of India and Provincial Governments, and later between the responsible adviser of the Government of India on medical matters and a junior officer. Now that it has been rendered vacant it should be allowed to die a natural death, as the Inspector-Generalship of Excise should too. If, however, it is found that in view of the increased activity in sanitary matters which is being displayed the work has grown too heavy for the Director-General of the Indian Medical Service to discharge unaided, the difficulty could be met by giving him a secretary solely for sanitary work.

We do not agree with the assertions above quoted, and we believe that such a step as the abolition of the Sanitary Commissioner with the Government of India would be a retrograde one. At no period in the history of Indian sanitation is such an appointment of more importance than at the present, and instead of reducing its status it might be well if the Government of India would appoint a surgeon-general of its Indian Medical Service to act as deputy to the Director-General, as has been carried out at the War Office for the British service. This would assure not only freedom from friction but an increased status to the incumbent of the post.

ALCOHOL AND INSANITY.

THE July number of the *British Journal of Inebriety* contains, in addition to a short introductory address by the President, Dr. Theo. B. Hyslop, on the Work of the Society for the Study of Inebriety, a valuable and interesting paper by Dr. F. W. Mott on Alcohol and Insanity. Dr. Mott has already dealt with this question in several communications, notably in a paper in the *Archives of Neurology* (Vol. III.), in a *rapport* to the International Congress of Psychiatry at Amsterdam on the Psychoses of Chronic Alcoholism, and in a paper on the Nervous System in Chronic Alcoholism read before the Pathological Section of the British Medical Association last year. In this further contribution to the literature of the subject he reiterates the views expressed in his earlier papers, and furnishes additional statistical evidence in their support. In opposition to what used to be, and in some quarters is perhaps still, the current opinion, Dr. Mott maintains that alcoholic excess is not a very important cause of insanity, and he holds that the exaggerated estimate formerly entertained of its influence in this respect is due to the failure to discriminate between what is really the result of alcoholism and what is innate and due to inheritance, the confusion arising from the fact that intemperance is so frequently an early, possibly the earliest, sign of mental breakdown. Arguments in favour of this view may be found in many different orders of facts, but the most conclusive are unquestionably those which Dr. Mott has drawn from the data of pathology. He has been able to compare the records of 2000 post-mortem examinations at Charing Cross Hospital with the records of a similar number at Claybury Asylum, with the result that, whereas in the hospital series there were 110 cases of cirrhosis of the liver, 60 per cent. with ascites, in the asylum series there were only 23 cases of cirrhosis, and among these only one case with ascites. These figures are hardly reconcilable with the view that alcohol is the important factor that asylum statistics appear to show. And, further, Dr. Mott points out that with regard to this matter the clinical facts agree with the pathological evidence, for the instances of mental affection of distinctively alcoholic character and resulting from the continued direct or indirect action of alcohol upon a relatively healthy brain are comparatively few, while the cases of insanity with a history of alcoholic excess, but occurring in persons of innately defective organisation, are numerous, and, moreover, in their clinical features are hardly, if at all, distinguishable from insanities occurring in abstainers. On the vexed question of the effects of parental alcoholism on the offspring Dr. Mott takes the eminently sane view that, while it is contrary to reason to suppose that the germ cells can remain unaffected in conditions involving prolonged toxic influences, yet it is necessary to have data of a more precise kind than any so far produced before we can attempt to give a definite estimate of the extent of these effects. None the less, it is Dr. Mott's considered opinion that parental alcoholism does undoubtedly lower virility, and that, at all events, when continued through successive generations, it must result in physical and mental degeneracy. The whole article may be commended as a most admirable and temperate statement of a question which is usually considered in a spirit to which these adjectives would certainly not be applicable.

THE ANNUAL DINNER OF THE MEDICO-LEGAL SOCIETY.

THE Insurance Bill naturally formed the subject of most of the speeches and conversation at the annual dinner of the Medico-Legal Society at the Holborn Restaurant. The dinner was held on July 20th, under the presidency of Sir John Tweedy. Among those present were Earl Russell, Mr. Rigby Swift, M.P., Sir Henry Morris, Sir William Collins, Sir Frederic Hewitt, Mr. Charters J. Symonds, Dr. W. H. Willcox, Dr. F. J. Waldo, Mr. C. Herbert Smith, and Mr. Walter Schröder. Mr. Rigby Swift, in proposing the toast of "The Medico-Legal Society," said that the society was an evidence of the interdependence of two great professions. He recalled his early memories of the old-fashioned family doctor, who was not merely a doctor, but the true friend and confidential family adviser generally. As to the legal relations of medical men, he had almost invariably found the medical profession earnestly endeavouring to assist in the administration of justice. Of late, medical men had more than ever been engaged in the courts, especially under the Workmen's Compensation Act, and now they seemed likely to have still more official work under the Insurance Bill. There was no doubt that the doctors would earnestly coöperate in such a movement for the public good if only they were offered fair terms: so such terms must be inserted in the Bill as would allow them to retain their independence and afford them adequate remuneration. Sir John Tweedy, in replying, spoke of the growth of the society both in numbers and in importance. He earnestly wished the legal members a continuance of their prosperity, because, if the Insurance Bill passed in its present form, a large part of the medical profession would find their occupation gone, and they would have to look to their prosperous

legal brethren to pay the fees of the pious but impecunious doctor. Sir William Collins, in proposing "The Guests," said that both the critics and the supporters of the Bill felt that legislation was proceeding too quickly, for it was not a subject that lent itself to hustling. The society might prove of great use to the officers of the Crown by helping the discussion of the matter in mixed meetings of lawyers, medical men, and laymen. The discussion of the Bill made it clear that almost every detail involved a principle, and the fact that these principles had not been thoroughly threshed out by those affected rendered the ultimate form of the measure uncertain. Its too precipitate passage could result only in considerable resentment. Mr. C. Herbert Smith proposed the health of Sir John Tweedy, who, in replying, mentioned that the Royal College of Surgeons of England had acceded to the request of the society to put aside a part of its museum for a medico-legal museum, and he appealed to the members to present specimens, so that in time they might have a medico-legal museum that should rival the famous museum at Edinburgh.

THE RARITY OF TABES AND GENERAL PARALYSIS IN THE NEGRO.

THE rarity of the so-called parasyphilitic affections among members of the coloured races has often been commented on. Among the numerous peoples of Africa, black and brown alike, syphilis is very rife, but tabes, according to the evidence of many observers, is most infrequent. In the coloured races of the United States it is much less common in the negro than in the mulatto, and still less in the latter than in the white. In view of the almost universal prevalence of syphilis among negro races this peculiarity is the more striking. Neurologists and syphilographers are wont to assert that untreated syphilis is prone to terminate in systemic degenerations of the central nervous system, yet the temperament of the negro is such as to render most attempts at treatment of syphilis futile, if it is not neglected altogether. In spite of these facts, and notwithstanding that he is also addicted to alcohol, the negro is curiously immune, and we must suppose that he is protected by something native to his organism. Dr. E. M. Hummel of New Orleans, who has had abundant opportunity of observing the effects of syphilis in a coloured population, reports in a recent number of the *Journal of the American Medical Association* a case of tabes in a full-blooded negress, aged 27. The menses began at the age of 12 and were apparently normal. One and a half years later the patient, then a girl of 13½, bore a healthy child, who is living and well. A dead child was born 3½ years later, and a miscarriage occurred 2½ years subsequently. It seems obvious that between the age of 14 and 17 the patient acquired syphilis; in any case the cardinal symptoms of tabes were established three years before she came under observation. Dr. Hummel comments on the great rarity of the condition, and refers to a point which has often attracted his attention. The subjects of tabes are for the most part from a class of the community who work assiduously, both with mind and body, who are apt to allow the worries of life to impress them unduly, who, in a word, present temperamental and nervous defects that seem to exert a certain influence in lowering powers of resistance. But the negro is notoriously a child, and to this day, thanks to his primitive limitations, still enjoys what Dr. Hummel calls the "childlike euphoria of a care-free life." Another interesting and curious fact has been noted by Dr. Weisenburg of Philadelphia in this connexion. He has remarked that in his experience tabetics nearly always have blue or grey eyes, and otherwise blonde complexion. In the neighbourhood of New Orleans people of Latin descent, nearly all brunettes, predominate, and Dr. Hummel has found that they are less prone to tabes than blondes. If the observations are of any significance they may mean that constitutions associated with a degree of pigmentation of the skin are somehow less liable to the toxin of such a disease as tabes. Biometricians and Mendelians are now working alike on lines which may here assist the clinician.

BRITISH PHARMACEUTICAL CONFERENCE.

THE British Pharmaceutical Conference, which met this week at Portsmouth, is approaching the fiftieth year of its existence. Since it came into being 48 years ago the Conference has contributed very largely to the advancement of pharmaceutical science, and the character of the papers contributed at this week's meeting indicates that it continues to fulfil the useful purpose for which it was founded. The subjects, which were for the most part of a purely pharmaceutical nature, were treated in a practical and concise manner, there being an entire absence of those lengthy and inconclusive communications which sometimes occupy considerable time at meetings of this kind. The papers are alluded to in some detail elsewhere in this issue, but special attention may perhaps be usefully drawn to one or two of outstanding interest. The variability in the therapeutic value of thyroid preparations is frequently a source of disappointment to medical practitioners, and the suggestion that an iodine standard should be fixed will be welcomed. Another medicinal product which varies considerably in activity is extract of Indian hemp, and no doubt the compilers of the British Pharmacopœia will have their attention directed to the suggestion that the official process of preparing this product should be altered; for the difference in the value of the extracts on the market is certainly unfortunate both for the medical practitioner and his patient. The compilers of the Pharmacopœia will also find some suggestive material in the paper on Podophyllum Emodi; the Indian podophyllum has been recognised in the Indian Addendum, and the question is under consideration whether it should be included in the forthcoming edition of the Pharmacopœia. The paper on opium assay by two well-known collaborators constitutes a valuable addition to pharmaceutical literature, and we much hope that they will find time to continue their investigations of this important subject. The results of the analyses of diabetic foods certainly demonstrate the desirability of placing some kind of restriction on the sale of this class of foodstuffs. In addition to the discussions of scientific subjects, matters of a more general character such as the sale of secret remedies and the position of the pharmacist in relation to the National Insurance Bill were considered.

GENERAL SUBCUTANEOUS ŒDEMA AS A FAMILIAL AFFECTION.

THE series of cases of general subcutaneous œdema associated with diarrhœa occurring in one family, recorded by Dr. F. H. Edgeworth on p. 216 of THE LANCET of July 22nd, constitutes a remarkable, if not a unique, contribution to the literature of familial affections. Of six infants born of healthy parents, all but one have died in the first few weeks or months after birth with general œdema following upon diarrhœa. The surviving child, now 2½ years old, also suffered from slight diarrhœa and œdema of the face during the second and third months of his life. Two of the cases have been carefully observed by Dr. Edgeworth, who found no evidence of renal disease during life or post mortem, and in a third case observed by Dr. G. S. Page the urine was normal. In one of the cases there was some increase in the coagulation-time of the blood, as estimated by Wright's method. Dr. Edgeworth discusses the nature of his cases in his interesting paper. The

occurrence of nephritis was definitely excluded in the two cases which came to necropsy. He gives reasons against regarding them as examples of œdema neonatorum which seem to us convincing. He suggests that the immediate cause of the œdema in his cases may have been the action of poisons absorbed from the alimentary canal, but he makes the further suggestion that there may have been an inborn defect in the walls of the capillary blood-vessels, rendering them more susceptible to poisons circulating in the blood than the capillaries of normal individuals. The explanation sometimes given of functional or orthostatic albuminuria is somewhat similar—viz., that the kidney in these cases is more permeable to the protein molecule than normally, and that this permeability is more easily influenced by slighter causes. Dr. Edgeworth points out that his suggested explanation is capable of being extended to include certain other conditions of œdema of obscure nature, such as general dropsy of the fœtus, apart from anatomical defects in the placenta and fœtal organs, hereditary trophœdema or Milroy's disease, and also the susceptibility of some individuals to erythemata and urticaria. There can be no doubt that the careful recording of cases of familial diseases is bound eventually to enlarge our knowledge of many obscure conditions of inherited disease and defect, and Dr. Edgeworth's interesting note may serve to bring to light similar cases to his own. It will be interesting to know the future history of the surviving case, more especially as to whether attacks of diarrhœa are associated with œdema in this child.

BRITISH DENTAL ASSOCIATION: ANNUAL MEETING.

FOR three interesting reasons the annual meeting of the British Dental Association, to be held next week at the University of London, South Kensington, will have special importance. It will be the first dental gathering that has taken place at the University; the attendance will certainly reach the highest figure on record, as the membership of the Association has increased to over 2000; and this year, by a happy coincidence, the International Dental Federation is also meeting in London. Both the Federation and the Association will have Mr. W. B. Paterson, F.R.C.S., L.D.S., for President. Some distinguished foreign dentists from America and the continent are taking part in the opening session of the International Dental Federation at the Royal College of Surgeons of England on Tuesday, August 1st, when they will be welcomed by the President, Sir Henry T. Butlin. A banquet follows in the evening at the Hotel Cecil. On Wednesday Professor Jessen of Strasburg presides over the Hygiene Commission, and Dr. E. C. Kirk of Philadelphia over the Education Commission, both meetings being at the University. The British Dental Association begins its meeting with a reception and dance given by the Metropolitan branch at the Hotel Cecil on Wednesday night. On Thursday the annual meeting of members takes place at the University, when the new President (Mr. Paterson) and some honorary members will be inducted. Thirteen papers will be discussed on Friday, including contributions on School Dental Treatment and its Results, by Mr. A. E. Baker, Mr. C. E. Wallis, and Mr. G. Cunningham (Cambridge); Bread-stuffs and the Experimental Production of Dental Caries, by Mr. A. Hopewell-Smith; and Tuberculosis and its Bearing on Dentistry, by Dr. Noel D. Bardswell, medical superintendent of the King Edward VII. Sanatorium at Midhurst. Some 27 demonstrations will occupy Saturday morning and afternoon, and a number of clinical cases will be on view. A museum, illustrating affections of the periodontal membranes, will be arranged in the entrance hall of the University. On Thursday the annual dinner of the Association will take place at the Hotel Cecil, and on Friday a conversazione will be held at the Royal College of Surgeons of England. Lunch will be provided each day in a marquee in the University quadrangle. The foreign visitors and the members of the Federation will be the guests of the Association at its meetings and social functions.

SCLEROTIC OR "WOODEN" THYROIDITIS: RIEDEL'S DISEASE.

IN 1896 Riedel published a description of two cases of a condition to which he gave the name "eisenharte strumitis," and in subsequent years observations of a similar nature were recorded by the same writer and by others, bringing the total number of cases up to 13. To these three more have been added by MM. X. Delore and H. Alamartine, together with a summary of the whole subject, in a paper in the *Revue de Chirurgie* of July 10th From this summary it appears that the clinical picture is remarkably like that of thyroid cancer, though in one of Riedel's cases a child of four was attacked. The commonest age, however, is during the fourth decade. More than half the recorded cases have been in men. A distinctive feature is the rapid evolution of the disease. In a few months, or even weeks, a tumour develops which produces serious effects by compression of the trachea and the recurrent laryngeal nerves; the laryngeal palsy is accompanied by dangerous paroxysms of dyspnœa. On the other hand, it is unusual to find any evidence of pressure on the sympathetic nerves or upon the œsophagus. The tumour is diffuse, involving the whole gland; it is extraordinarily hard and firmly fixed to surrounding structures. Its surface is smooth and does not adhere to the skin. The neighbouring lymph-glands do not show any striking enlargement. To the naked eye the diseased area appears whitish and homogeneous; it is very hard to cut. Microscopically nothing is found except a free formation of dense fibrous tissue of an inflammatory type; not even at the edge, where the disease is binding the thyroid gland to the neighbouring muscles and fasciæ, is there the least sign of malignant disease. It is possible that in some of the recorded cases either tuberculosis or syphilis has played a part; but in the majority of instances no definite cause could be named. Fortunately, this distressing disease seems to be amenable to treatment. Several cases have been successfully treated by thyroidectomy; but this is not to be advised, as the free adhesion to surrounding tissues greatly impedes the operator and exposes the patient to the dangers of hæmorrhage. Liberation of the trachea by cuneiform resection of the thyroid isthmus gives speedy relief to the symptoms, and is usually followed by a rapid disappearance of the disease. If there are no severe pressure symptoms milder measures may suffice; and especially radiotherapy should be tried, for the X rays appear to have an almost specifically curative effect.

THE London County Council on July 25th resolved: "That Section 55 of the Public Health (London) Act, 1891, with respect to the notification of infectious disease shall apply in the administrative county up to and including March 12th, 1912, to acute polio-myelitis or acute polio-encephalitis." The Public Health Committee informed the Council that the disease known by these names had engaged attention in recent years in Europe, especially in Norway and Germany, as well as in the great cities of the United States of America. The disease, which occurred principally among children, proved fatal in about 11 or 12 per cent. of those attacked, and was responsible for the production

among those who survived of infantile paralysis. In the northern hemisphere occurrence of the disease was noticeable mostly in the summer months, and as in some instances multiple attacks had occurred in the same households, schools, or streets, these had been attributed to infection from one person to another. Early this year the Royal College of Physicians of London asked the Council to make the disease notifiable, and the Public Health Committee thought the request should be acceded to, as there was a possibility of cerebro-spinal meningitis being mistaken for polio-myelitis.

THE REORGANISATION OF PUBLIC HEALTH ADMINISTRATION IN THE COUNTY OF LONDON.

THE General Purposes Committee this week reported to the London County Council on the subject of the reorganisation of medical inspection and treatment and school medical work generally, and we are glad to observe that the committee declared itself strongly in favour of the policy adumbrated in THE LANCET on several occasions—viz., of coördinating all this work in the existing public health administration, instead of, as the Education Committee proposed, placing it under the control of a layman—the education officer, Mr. Blair.[1] The proposed reorganisation will hasten the retirement of Sir Shirley Murphy, but the Council will retain his services in a consultative capacity for at least two years.

By way of preface the General Purposes Committee remarked that from among the otherwise conflicting views held on this subject by the committees affected, one fact clearly emerged, and that was that the present arrangement by which medical inspection was dealt with in the Public Health Department and medical treatment in the education officer's department could continue no longer. The question, therefore, resolved itself into the fundamental one, Should the whole of the work be entrusted to the department which dealt with medical work and had for its chief officer a medical man, or should it be included in the department of the education officer. On this point suggestions were invited from the officers concerned. The principle underlying the education officer's scheme was expressed by him when he suggested that one officer should be responsible to the Education Committee for the general organisation of every branch of the education service. The principle upon which the medical officer's scheme proceeded was that upon which the organisation of the whole of the Council's work had been based hitherto—viz., that all work executed by the Council, whether administrative or professional, which was involved in the exercise of a particular profession, should be done in the department and under the direction of the professional officer concerned. Thus architectural work in the schools was associated with the other architectural work of the Council and placed under the control of the architect. Education financial work was associated with the other financial work of the Council; education stores came from the General Stores Department; education legal work was dealt with by the Council's solicitor, and so on. On first principles, therefore, it was evident that a natural and proper course was for medical inspection and treatment to be administered in the Public Health Department, in conjunction with the other medical work of the Council, under the control of the professional officer at the head of the medical department. The General Purposes Committee dealt *seriatim* with the principal arguments of the Education Committee in favour of the contrary policy. The Education Committee thought that having regard to the existence of 29 sanitary authorities in London there would be difficulty in placing the school medical work under the county medical officer of health, and that what was especially needed was the coöperation of the 29 local medical officers of health. The General Purposes Committee did not appreciate this difficulty, holding that the desired coöperation was more likely to be secured by the Public Health Department, which was constantly in touch with the local medical officers of health. The Education Committee urged that the school medical work was closely associated with the general activities of the schools and the general machinery of education administration. The General Purposes Committee replied that this was no doubt the case, and whatever system was set up the coöperation of teachers and others would be an important element. There was no reason why such coöperation should not be given to the Public Health Department.

[1] THE LANCET, March 4th, p. 627, and 18th, p. 760.

The Drawbacks to Lay Control.

Special difficulties of organisation and administration were likely, in the opinion of the General Purposes Committee, to arise from the adoption of the Education Committee's proposal. This appeared to be recognised by the inclusion of provisions of an unusual nature—viz., that although the work of the medical officer (education) should be placed under the control of the education officer the former should have the right of access to subcommittees. The General Purposes Committee regarded such an arrangement with considerable apprehension. Apparently it was not intended that medical men should supervise the administrative details of school medical work, although such work must depend to a large degree upon their expert advice. Further, the system under which both the education officer and the medical officer (education) would report upon school medical work would be likely to lead to one of two results—the professional but subordinate officer, feeling the difficulty of his position, would either qualify his reports so as to meet the views of his superior though non-professional head, or he would maintain his views with the result that conflicting advice would be given from the same department. Should a decision be given in favour of the views of the subordinate officer a difficult situation might be created and the responsibility of the head of the department be weakened. It would be impossible under such an arrangement to fix the responsibility for action of any kind, and impossible for committees and for the Council to depend upon receiving the unfettered opinion of the professional officer upon the results of his own work or upon the estimated results of new proposals. Under the Council's system of organisation into departments these difficulties were avoided, as there was only one responsible head, and he was rightly held responsible, not only for the advice he gave, but for the results of following it. His professional reputation was the foundation upon which the Council relied for the best possible advice on matters within his province, and this system had worked with uniform success. It should be pointed out that placing medical inspection and treatment in the education officer's department would involve also the transfer to that department of the other duties hitherto performed by the medical officer (education), including the work of dealing with epidemic and infectious diseases in the schools. It was evident that in this matter prompt administrative action was of first importance, and that the responsibility for such action and its results could rest only with a medical man. In all the circumstances the committee did not think the case could be regarded as so exceptional as to justify such an important departure from accepted policy as the placing of medical expert and administrative work in the department of a lay officer. The often expressed desire of the Board of Education that the school medical officer should be responsible for the medical work could not possibly be secured under such a system, and it was at least doubtful if the Board could approve the appointment as school medical officer of an officer the arrangements for whose professional work were made by another officer entirely independent of him.

Reorganisation of the Public Health Department.

On the fundamental grounds of organisation the proper course was to place medical inspection and treatment of school children under the direction of the county medical officer of health. It was a sound principle that the same health organisation should deal with the individual before, during, and after school age, and that the department which was concerned with limiting the spread of infectious and epidemic diseases in the community should not be precluded from dealing with such infectious diseases in children, whether in school or at home. It followed that the county medical officer of health would exercise supervision over the school medical work generally. This would necessitate a reorganisation of the Public Health Department, and in considering this aspect of the question the General Purposes Committee had had regard to the fact that Sir Shirley Murphy, the

county medical officer of health, would retire under the age limit in less than two years' time. Seeing that the present proposals involved for the Council's medical officer a much enlarged responsibility, and entailed on him the serious and protracted task of amalgamating and coördinating the previously divided functions already referred to, the committee viewed with apprehension the nearness of the retirement of Sir Shirley Murphy. A period of less than two years in which to consolidate, harmonise, and leave in working order functions hitherto divided was all too short for any man, and to call on the present medical officer to undertake the responsibilities, creative and administrative, that were involved, and this on the eve of his departure, would be out of the question unless his retirement were almost indefinitely deferred. The committee had conferred with Sir Shirley Murphy on the subject in all its bearings, and he had stated his desire to place himself in the hands of the Council, so that the reorganisation of the Council's medical work might be effected under the best possible conditions.

The Position of Sir Shirley Murphy.

After careful consideration the committee advised the Council to arrange for Sir Shirley Murphy to relinquish duty as chief medical officer of the county at a date not later than Dec. 31st, 1911, while retaining his services in a consultative capacity for a further period, so that his successor should have the advantage of his large experience, particularly in the details of medical administration. Sir Shirley Murphy entered the London County Council service in 1889, being the first chief officer appointed by the Council and the first medical officer of the County of London. His services to London, said the General Purposes Committee, were in no need of eulogy; the decline in the figures of the death-rate during the administration of the Council testified to the fruitfulness of his labours, while the honour of knighthood conferred upon him in 1904 recorded the high regard in which Sir Shirley Murphy's work in the cause of public health was held. The committee was sure the Council would feel great regret at Sir Shirley Murphy's retirement and would desire to grant him the maximum retiring allowance. Sir Shirley Murphy had served the Council for 22 years, and if his service had come within the Superannuation (Metropolis) Act, 1866, the Council could, by adding ten years to his service, have granted him an allowance of 32 sixtieths of his salary. The committee therefore proposed that the Council should supplement his retiring allowance by such an amount as would bring the allowance up to £666 13*s.* 4*d.* a year—viz., 32 sixtieths of his salary of £1250, and retain his services in a consultative capacity for two years from the date of his retirement at such a remuneration as would not exceed, with the retiring allowance, his present salary. Steps would be taken as soon as possible to fuse the work of medical inspection and treatment in one department under the medical officer before the appointment of the new medical officer.

In conclusion, the committee referred to the anxiety expressed by the Board of Education to know at once the Council's proposals to meet with the present situation. If the present proposal was adopted and laid before the Board in its entirety and followed up with the detailed scheme prepared by the Education Committee for carrying out school medical inspection and treatment,[2] the Board would see that the Council had dealt with the matter in a strong and effective way, and would agree, the committee thought, to accept the Council's proposals as the proper method of organising school medical work. The committee promised to follow its present report with another next week detailing the arrangements to be made consequent on the retirement of Sir Shirley Murphy.

At the meeting of the Council it was evident there was general agreement upon the proposals of the General Purposes Committee and discussion was very short.

An amendment was moved on behalf of the Education Committee that the proposals of the General Purposes Committee should not take effect until Jan. 1st, 1912. It was urged that the Education Committee was under a pledge to the Board of Education to make the scheme of medical treatment effective by October next. If between that date and Christmas the whole of the administrative work was transferred to another department it would seriously handicap the Education Committee in the effort to carry out the wishes of the Board of Education.

The amendment was agreed to and the recommendations of the General Purposes Committee were then approved.

[2] THE LANCET, July 22nd, p. 246.

THE NATIONAL ASSOCIATION FOR THE PREVENTION OF CONSUMPTION.

THE annual conference of this association took place at the Caxton Hall, Westminster, on July 19th, 20th, and 21st.

Among those present at the opening, when Sir WILLIAM YOUNGER presided, were the President of the Local Government Board (Mr. John Burns), Sir Thomas Barlow, Sir William Osler, Professor Sims Woodhead, Dr. A. Newsholme, Dr. T. D. Acland, Dr. E. W. Hope, Dr. J. E. Squire, Dr. James Kerr, Dr. J. Niven, Dr. J. J. Perkins (honorary secretary of the association), Sir W. Treloar, Mr. Waldorf Astor, M.P., Mr. G. Harwood, M.P., Rev. P. Clementi Smith, Miss MacGaw, and a number of delegates from local authorities and institutions all over the country.

Sir WILLIAM YOUNGER first read the following telegram from the King:—

As patron of the National Association for the Prevention of Consumption and Other Forms of Tuberculosis, I congratulate all who will take part in the annual conference which assembles to-morrow. I sympathise deeply with the association's work, so far-reaching in its influence upon the future of the human race. I note with interest the important questions to be dealt with at the conference, and the names of the eminent authorities by whom the meetings will be conducted and addressed.

Opening of the Conference by Mr. John Burns.

Mr. JOHN BURNS expressed his pleasure in attending to open this useful, practical, and human conference, which brought a message of hope to an army of 300,000 people in these kingdoms suffering from tuberculosis in one or another of its forms. The "man in the street" was now determined to coöperate with the medical officer of health, the town and county council, and the private practitioner in this important work. Estimated by its victims tuberculosis in all its forms was a declining disease, and its annihilation ought to be effected in 25 to 30 years till it became only a memory, just as typhus, leprosy, and the plague were now. In ten years consumption had diminished in England and Wales 19 per cent., in Scotland 24 per cent., in Ireland 24 per cent., in Germany 18 per cent., in London 30 per cent., in Berlin 24 per cent., and in Paris only 3 per cent. In 50 years tuberculosis had declined 50 per cent. for all ages, while for the period from birth up to 25 years it had declined 70 per cent. These were encouraging figures. It was interesting to note that the general death-rate also had declined 26 per cent.—27 per cent. in London—and the infant mortality 30 per cent. in the same period. Another significant thing was that coincidently with this decline in the tuberculosis and general death-rates and in infant mortality the national drink bill had diminished from £4 12*s.* to £3 8*s.* 11*d.* per head—a diminution of 25 per cent. in the consumption of alcoholic beverages. The decline of consumption was concurrent with increasing sobriety, better housing, growing education, and the social and moral elevation of the people. To the ratepayer Mr. Burns pointed out that £160,000,000 were paid every year for health and social service. Out of 4000 Poor-law consumptives in Liverpool, 60 per cent. were paupers because they were consumptive. Pauperism and tuberculosis acted and reacted on each other, tubercle being the pauperiser, and pauperism the seed plot of tubercle. He gave a simple illustration as to the value of remedies under the existing law quietly enforced. In 1875 the death-rate in the London garrison of the Guards was 20·4 per 1000 among strong, young, presumably healthy men. To-day it was not more than 3 per 1000, or seven times less. The same barracks were in use, but they were cleaner; the windows were more open, and the soldier had adopted the increasing sobriety of the nation, and this combination had brought about the reduction. Similar figures could be shown for the navy and other sections of society. Another factor in the reduction was high wages if accompanied by wise spending. Mr. Burns warned his hearers against dogmatising on any special means of combating tuberculosis. Much could be done by applying some

of the new methods, but the good could be increased by exhausting all the agencies calculated to secure the object they all had in view. Mr. Burns then dealt with the great advance made by the local authorities in regard to the notification of cases of tuberculosis from Poor-law institutions and hospitals, and said that the duty incumbent on them was clear in view of the facts that from 30 to 50 per cent. of the cost and numbers of pauperism was due to sickness, most of which was consumption, that 75 per cent. of the cripples had a tuberculous origin, and that 90 per cent. of hunchbacks, 75 per cent. of the scrofulous, and 50 per cent. of those who had convulsions were inflicted with the disease. The Local Government Board was authorising local authorities to establish dispensaries, to purchase cheap and portable shelters for use in yards, to procure and distribute literature. Local authorities were more active in enforcing the unsound food regulations, and the milk and dairy trade had been vastly levelled up. The Royal Commission, after ten years of unpaid, disinterested, self-sacrificing, painstaking research, had issued its fourth and final report, which justified the demand for new milk legislation. A Milk Bill was essential and urgent, and before many months were over the milk and dairy industry of the country must be placed on a clean, sound, healthy, and permanent basis. Mr. Burns referred to the funds and income to be provided under the Insurance Bill for the establishment and upkeep of sanatoriums, and was confident that the money would be expended wisely and well. He did not doubt that some local authorities would accept the Chancellor's offer of half the cost for the wives and children of insured persons in sanatoriums, if the local authorities would bear the other half, and that others would soon follow.

Professor SIMS WOODHEAD advocated the inclusion of hygiene in the curriculum of secondary as well as elementary schools. He commended exhibitions and lectures and caravans, and the work of district nurses and health visits as educational methods, and said that good educational work had been done by the Royal Commission. There was sure to be criticism of the latter, but such criticism only showed that the public was becoming alive to the subject. He dwelt on the influence of alcoholism as a predisposing factor. But there was no universal panacea for the disease; the educational crusade must be a broad and common-sense one, not too insistent on any one method, but covering all.

Dr. F. C. SHRUBSALL, assistant school medical officer of the London County Council, in a paper on

The Place of the School in the Campaign against Tuberculosis,

pointed out that in the early educational stages the work against tuberculosis consisted in the inculcation of personal hygiene. There might come a time when a bath would form part of every elementary school in large towns, as it did in Germany, Holland, and Scandinavia. One bath was worth a hundred lectures, and cleanliness of clothing would follow cleanliness of body. Next winter the Council would provide a course of lectures for teachers, showing how they could assist the antituberculosis campaign. Strict isolation of sufferers might reduce the prevalence, but it might conceivably lessen the natural resistance of the community. The most effective guard was to cut down the modes of dissemination, which really meant universal cleanliness. Public opinion, by a rigid standard, could diminish tuberculosis and those minor affections that paved the way for it.

Sir WILLIAM YOUNGER, in a paper on

Tuberculosis Exhibitions and Caravans,

spoke of the value of travelling caravan exhibitions, such as that in his own county of Dumfriesshire, which with the lectures to children and adults did much good. The visit of the caravan also might induce property owners to remedy defects in their properties that were injurious to health.

Mrs. HOWARD MARSH, in a paper on

The District Nurse and the Health Visitor,

described the work of the Cambridge branch of the League for Physical Education and Improvement in Health Visitation. Those mothers who had followed the visitors' course were allowed to enter their children to compete in an annual baby show. The prizes were a Savings Bank book in which a shilling or two had been placed to the credit of the best babies in each of four sections—viz., weight, firmness of flesh, thickness of bone, general well-being—with mugs as consolation prizes for the unsuccessful. She insisted on the necessity of character, adequate training, interest in the work, and a sense of humour for health visitors.

Mr. J. LISTER STEAD, secretary of the Ancient Order of Foresters, in a paper on

Propaganda among the Friendly Societies and Trade and other Organisations of the Working Classes,

insisted on the close connexion between poverty and tuberculosis. The fact that at least that part of the Insurance Bill dealing with tuberculosis had received general approval was a gratifying recognition of a greater national responsibility in a matter which up to now had been left to private enterprise. The statistics of the Foresters showed that in a period of five years 15·23 per cent. of all deaths were due to phthisis, while those of the Hearts of Oak showed that the consumptive members in a period of ten years received average sick pay 75 per cent. in excess of that to all other members.

At the afternoon session of Wednesday, July 19th, Sir WILLIAM OSLER presided.

The Value of Family Inspection and of Notification.

Dr. R. W. PHILIP of Edinburgh said that tuberculosis in the adult was in large part a development from tuberculosis in the child. The need was for early detection, and the teaching of hygiene enabled every intelligent person to be in some degree a detective officer. Medical students needed better training in physical and bacteriological methods. He urged a revision of the methods of out-patient departments, and said that the whole family should always be inspected whenever a case of tuberculosis was discovered. In Edinburgh no inconvenience had arisen from compulsory notification, and this system had extended in Scotland from eight authorities in 1907 to 74 in 1910, and more than half the notifications in Edinburgh came through the dispensaries. He commended the plan of linking the London dispensaries together through the intermediary of a central council.

Dr. CECIL WALL, assistant physician to the London and Brompton Hospitals, read a paper on

The Hospital Out-patient Department as a Machine for the Detection of Pulmonary Tuberculosis,

and referred to the effect on the hospitals if the Insurance Bill became law. The only members of the community then remaining unprovided with medical attendance would be children under the school age, those between 14 and 16 who were unemployed, unemployed women, and people between 65 and 70 years. The hospital out-patient departments would retain only consultative functions, and he suggested that each out-patient department should be constituted a consulting centre for a definite district for the diagnosis and treatment of tuberculosis.

Dr. JAMES NIVEN described the work done in Manchester. He urged compulsory notification, additional sanatoriums, and the placing of funds at the disposition of the medical officer of health. If the sanatorium benefits under the Insurance Bill were to be separately administered the work would be impaired. Sanatorium benefit under the Bill should depend on notification having been made to the medical officer of health.

Dr. HALLIDAY G. SUTHERLAND, of St. Marylebone Dispensary for Consumption, in a paper on

The Tuberculosis Dispensary,

said that the dispensary formed a centre from which the majority of consumptives were treated—a clearing-house through which suitable cases could be distributed among open-air schools, sanatoriums, farm colonies, and hospitals for advanced cases, and a base from which organised search could be made for early and undiagnosed cases.

Other speakers were Miss M. E. BIBBY, Miss HETTY COWEN, and Dr. E. W. HOPE.

On July 20th Sir RICHARD DOUGLAS POWELL presided at the morning session. He said that the cases with which they had to deal were of two classes—the annual crop of new cases and the residuum of tuberculous population. By dealing with the first successfully the second would cease to be recruited and would die out. They had to learn what was best for each group of cases. Meanwhile, acquired and hereditary immunity had probably long been lessening the proclivity to tuberculosis in civilised communities.

Sir WILLIAM OSLER, in an introductory address, spoke of the universal diffusion of tuberculosis. What was necessary was education, not only of the public, but of the profession.

There was too much carelessness in examination among doctors, and that would tend to increase under that worst of all systems that was to be forced upon the profession—contract practice. The tuberculous patient needed to be under strict control by a capable doctor and a good nurse, and had to work out his own salvation with courage and hope. Hardly 10 per cent. of the cases could be treated in sanatoriums, so the home treatment must be developed. He urged closer association of the tuberculosis dispensaries with the general hospitals, whose duty it was to take up the work with their laboratory facilities and their social service agencies. He dreaded the group of men whose whole work, knowledge, and life were spent in the tuberculosis dispensary; they must needs become narrow. A closer study of tuberculin was needed, for those who used it carefully and persistently had excellent results, which showed that properly used in suitable cases it had an undoubted efficacy. In a few years it would be better known to what extent and in what manner this remedy could be best used.

Dr. ARTHUR LATHAM, in a paper on

The Value of the Sanatorium Treatment,

said that the public had not grasped that in many cases, owing to the severity of the disease, sanatorium treatment must be useless, in a few cases actually harmful, and in many others need not be carried out in an institution. The cardinal factor was not fresh air and food, important as these were, but the constant and skilled regulation of the rest and exercise prescribed from day to day. Sir Almroth Wright's work had disclosed the reason for this fact, which had been clinically apprehended by Bremer and Walther. Movement determined the quantity of blood and lymph sent through the lung, and on this depended the amount of poison swept into the general circulation. It was the question of how much of this poison the defensive forces were adequate to cope with that regulated the amount of exercise allowable. Early sanatorium treatment gave more control over the defensive forces, so that in a large proportion of cases a man's capacity for work could be restored. This, added to the education that made him cease to be a danger to the community, was all the argument needed to support the claims of the sanatorium. That sanatorium treatment had not met with universal acceptance was due to the fact that many existing sanatoriums were inefficient, to the improper idea obtaining in some quarters that sanatorium treatment was sufficient in itself and a certain cure for consumption, and to the fact that hitherto sanatoriums had been too costly. Nowadays, apart from the land the initial cost should not exceed £100 a bed and the upkeep should be less than 25*s*. a week. The difficulty arising from the maintenance of the family in the absence of the breadwinner should be swept away by intelligent administration of the Insurance Bill.

Dr. JANE WALKER, medical superintendent of the East Anglian Sanatorium, in a paper on

The Sanatorium Treatment of Consumption,

said that most consumptives, even in the earliest stages, took far too little food, and that of unsuitable kinds. She emphasised the importance of adequate food, the overcoming of the dread of a draught, the importance of rest, and the inestimable value of work properly applied; she laid stress on walking. Work was not only physically useful but was a corrective to boredom, which was depressing.

Dr. MARCUS S. PATERSON discussed

The Educative Value of Sanatoria,

as also did Dr. J. J. PERKINS. The last-named described the method evolved by Dr. Arthur Newsholme at Brighton of utilising a block in the isolation hospital for such consumptives as, while still able to work, were advanced to a stage where it was impossible to obtain for them a lasting cure. For such cases some measure of treatment was necessary for them from time to time as their strength failed with continued work, and a short period of rest, feeding, and change of surroundings provided all the improvement possible. Such patients were ideal subjects for home treatment, but they would be able to carry out the necessary rule of life at home only if it had been thoroughly drilled into them in a course of sanatorium training. In such cases the educative value was paramount, the few weeks' treatment only incidental. After the patient's return home he was kept under surveillance by a band of workers.

Dr. J. EDWARD SQUIRE read a paper on

The Home Treatment of Consumptives under the National Insurance Bill.

He pointed out that it would be practically impossible to treat all cases of consumption in institutions during the whole period for which treatment was required. Few experienced people now expected arrest of the disease from three months' treatment, so that treatment must be continued at home under medical supervision. There must, therefore, always be consumptives in all stages of the disease needing to be treated at home. For these the National Insurance Bill made no provision beyond free medical attendance. It offered no supervision other than what obtained in some places for all, including the uninsured, on notification. The dispensary system provided the most useful and satisfactory provision for home treatment and supervision, but the Insurance Bill gave no such advantage. For the advanced consumptive the 10*s*. benefit would not allow of so keeping his house as to aid recovery or prevent the infection of others. There was no power to insist on the removal of a consumptive from a house where neglect of necessary precautions was a menace to others. When the State found part of the insurance funds it ought to be able to take necessary steps to prevent infection of those who were, or would be, insured at its expense. Sanatorium benefits under the Bill should be enlarged to include some of the requirements for home treatment, the loan of shelters for outdoor sleeping, the means of having a separate room, or at least a separate bed, extra milk, or suitable food. It was much to be desired that the National Insurance Bill should allow further consideration to the needs of consumptives who must be treated at home.

Dr. J. F. J. SYKES, medical officer of St. Pancras, read a paper on

The Relationship of Philanthropic and Municipal Agencies in Diagnosis and the Treatment of Persons under 16 Years of Age,

in which he said it was in the search for a diagnosis of disease in its early and premonitory stage that the coöperation of philanthropic and municipal agencies was most valuable. He suggested that hospitals and dispensaries should undertake to diagnose and report on the condition of contacts sent by health visitors. With regard to children under 16 the Poor-law guardians and the London County Council might take action under Section 34 of the Children Act of 1908 to commit such children if neglected to the care of some fit person or society for the protection of children, but the very bodies having executive duties in regard to consumptives—viz., the metropolitan borough councils—were purposely omitted from the Act. In a roundabout way their medical officers could search out ailing persons under 16, and report any neglect to the guardians, so as to obtain for them proper home or institutional treatment.

In the afternoon Dr. LATHAM presided.

Dr. RALPH P. WILLIAMS, school medical officer of health of Sheffield, contributed a paper on

Open-air Recovery Schools,

in which he said that about 7 per cent. of elementary school children were mentally dull, and in about half the mental dulness was due to physical defects, including early tuberculosis and conditions predisposing to tuberculosis. He described the Sheffield open-air school for such cases (which had resulted at a cost of £700 from the conversion of a disused elementary school), its staff, selection of children, their condition on admission, treatment of the teeth, feeding, milk-supply, personal hygiene, rest, shower baths, and the costs of maintenance. The results, as estimated by the examination of the children in October, 1910, were: cured, 44; improved, 51; in the same condition, 3. The open-air school was valuable for its educative influence on parents, teachers, and children; in providing education for those too delicate for the regular schools; in leading to the placing of simpler schools in suburbs rather than massive buildings in cities, and in taking classes in the playgrounds and stimulating nature rambles, as a means for the treatment of anæmia, malnutrition, and the pretuberculous stage. Schools of this type should be constructed to

accommodate at least 2½ per cent. of the elementary school population.

Miss MCGAW, in a paper on

Tuberculosis Schools,

said that the amount of tuberculosis among school children was estimated at from 5 to 3 per cent., but that was probably under the mark; for medical inspection of schools, as at present practised, was useless, as owing to shortness of time a sufficiently detailed examination to detect the early signs of tuberculosis could not be made, and children under 8 were merely inspected, not examined, unless they were thought to be ill. She spoke of the excellent results of the Edinburgh Special Antituberculosis School, and said that under the Elementary Education Act (Defective and Epileptic Children), 1899, the education authority had power to establish such schools. She urged the need of organising such schools in relation to some antituberculosis institution, so that close medical supervision might be available, with medical supervision of the home and the direction of the choice of occupation when school was over, in regard to the physical condition of the child. All schools should be open-air schools—i.e., they should all open their windows.

Dr. A. MAXWELL WILLIAMSON, medical officer of health of Edinburgh, in a paper on

Advanced Cases and Segregation,

pointed out that it was hopeless to talk of segregation until the essential preliminaries of notification, the establishment of sanatoriums for early cases, and dispensaries devoted to treatment and prevention had been established. He described what had been done in Edinburgh by the use of a pavilion of the infectious disease hospital for segregating late cases. Prior to the establishment of this hospital in 1905, 73 per cent. of deaths from phthisis occurred in the homes of the patients, 14 per cent. in the parish hospital, and 13 per cent. in other institutions. Four years later only 51 per cent. died in their homes, 20 per cent. in the city's hospital, 20 per cent. in the parish hospital, and only 9 per cent. in other institutions. He urged the rendering such hospitals markedly attractive to overcome the prejudice against them.

At the morning session on July 21st

Mr. C. S. LOCH, secretary of the Charity Organisation Society, read a paper on

The After-care of Patients.

He cited a series of cases to show the many factors that entered into the after-care. One must work through local agencies with comparatively small areas. Treatment without visiting would effect little. The establishment of dispensaries would aid in detection of contact cases. He criticised the proposed method of working of the sanatorium benefit in the Insurance Bill, saying that as the Bill stands, a large sum is to be contributed for sanatoriums, but that no suitable means were suggested to utilise the sanatorium properly from the point of view of the family needs in long and continuous illness. The cases he had adduced showed that some such provision should be made.

Dr. H. W. MCCONNEL read a paper on the same subject, in which he said that after-care was mainly dependent on individual effort acting in individual cases, and there was a great danger in sanatoriums supported by State funds that this individuality of the workers would be checked; that private interest and work would be superseded by officialism, which would be more expensive and less effective. The working patient scheme, whereby patients were employed in and about the sanatoriums for a small wage, would be hampered, because these workers would have to be insured, as the Bill stood, and the sanatoriums would have to pay the insurance. These difficulties might possibly be removed by working the State-paid sanatoriums through existing sanatorium machinery, and so keeping its individuality, and freeing all working patients where work is part of their treatment from the action of the Bill.

The rest of this session was given up to general discussion.

Mr. WALDORF ASTOR, M.P., read a paper on

The Economic Cost to the Community of Tuberculosis.

He referred to the well-known figures given in "The Conquest of Consumption" by Dr. A. Latham and Mr. G. H. Garland, and to the records of the German Imperial Office quoted by the Chancellor of the Exchequer in the House of Commons, and declared that with these and similar figures before us it is clear that the cost of sanatorium treatment, provided that only suitable cases are selected, would be repaid over and over again by saving in disablement benefits.

Dr. NATHAN RAW read a paper on

The Use of Existing Accommodation in Dealing with Tuberculosis,

in which he paid a complimentary tribute to Mr. Lloyd George's clauses with regard to the treatment of consumption in the National Insurance Bill. Dr. Raw advocated the taking over of existing institutions, such as small-pox hospitals, workhouses, and portions of fever hospitals, which are no longer required for the purposes for which they were constructed, and so to provide treatment for tuberculosis patients. In this way, a very large number of beds would be available throughout the country. Comparatively few cases, in his opinion, will receive any material benefit by such institutional treatment, but nevertheless the provision of large numbers of sanatoriums throughout the country will do more than anything else to stamp out the disease from our midst. Dr. Raw suggested that such sanatoriums should be divided into four groups: (1) For early cases, with a view to cure; (2) farm and industrial institutions for arresting the disease; (3) sanatoriums for advanced and hopeless cases; and (4) open-air schools and sanatoriums for children. He regarded the third group as by far the most important, and that the transfer to them of advanced cases should be compulsory, and that they should be constructed of the simplest materials which can be readily disinfected or destroyed.

Mr. ERNEST J. SCHUSTER, LL.D., read an interesting paper on this critical question:—

Will National Health Insurance Ensure National Health?

In a close *résumé* of the proposals under the National Health Insurance Bill, which are intended to affect the general hygiene conditions of the country, he found many of the proposed measures to regulate the general conditions of public health only of problematical value. With the exception of the case of excessive sickness, where inquiry is valuable, the proceedings under the Bill are likely, he thinks, to create an expectation which would probably not be fulfilled, and further, that the measures affecting the insured persons individually will not benefit national health to any appreciable extent unless they are largely supplemented by voluntary agencies. The importance of maintaining these agencies and supporting them with all possible energy by the side of any system of State insurance which may be adopted cannot be sufficiently accentuated and impressed upon the public.

IMPERIAL CANCER RESEARCH FUND.

THE annual meeting of the General Committee of the Imperial Cancer Research Fund was held on July 20th at the Royal College of Surgeons of England, the DUKE OF BEDFORD, K.G., the President, being in the chair. Amongst those present were Sir William Church, Sir Thomas Barlow, Sir Henry Butlin, Sir R. Douglas Powell, Sir John Tweedy, Sir Henry Morris, Sir Henry Howse, Sir John McFadyean, Sir Francis Lovell, C.M.G., Mr. Edmund Owen, Dr. Sidney Martin, Dr. F. W. Andrewes, Dr. T. H. Craig Stevenson, Mr. S. Forrest Cowell (secretary of the Royal College of Surgeons of England), Dr. J. A. Murray, Dr. W. H. Woglom, Mr. R. Clement Lucas, Lady Meiklejohn, Miss D. S. Coode, Dr. E. F. Bashford (general superintendent), and Mr. F. G. Hallett (secretary).

The adoption of the report was moved by Sir WILLIAM CHURCH in a speech which was a very able summary of the main points of the

NINTH ANNUAL REPORT.

Report of the Executive Committee.

The ninth annual meeting of the General Committee of the Imperial Cancer Research Fund was held at the Royal College of Surgeons on July 20th last, when the chair was taken by the Right Hon. A. J. BALFOUR, M.P. Sir WILLIAM CHURCH, Bart., K.C.B., chairman of the Executive Committee, presented the annual report, which was adopted. On the motion of Sir WILLIAM CHURCH, Bart., seconded by Sir HENRY MORRIS, Bart., His Grace the Duke of BEDFORD, K.G., was unanimously elected President of the Fund. Mr. BALFOUR, in moving a vote of thanks to the Chairman and members of the Executive Committee, the sub-committees, officers, and others, spoke of the valuable work done by the Imperial Cancer Research Fund the result of which

has been to open up entirely new lines of investigation, and laid stress on the fact that the main work of the Fund—its laboratory research—"is the only possible method of working which is going to produce great and permanent results for the good of humanity." Sir Richard Douglas Powell, Bart., K.C.V.O., was appointed a member of the General Committee and Sir Watson Cheyne, Bart., was re-elected a representative of the General Committee on the Executive Committee. It was also resolved—

"That the Honorary Treasurer of the Fund be, in future, *ex-officio* a member of the Executive Committee."

Mr. R. Clement Lucas was elected by the Council of the Royal College of Surgeons a member of the Executive Committee in the vacancy occasioned by Sir Henry Morris, Bart., becoming, as Treasurer, an *ex-officio* member. Professor Higuchi and Dr. Takaki of Tokio, Dr. Rosenthal of Budapest, and Dr. Snapper of Amsterdam, have returned to their respective countries after pursuing, by permission of the Executive Committee, various investigations extending over a period of several months in the laboratories. The General Superintendent has continued to make a liberal distribution of material to all, both in this country and abroad, who have applied to him, and it is with satisfaction that an exchange of valuable material with Japanese scientific workers can be reported. To Professor Honda, Director of the Imperial Naval Medical College at Tokio, and to Dr. Higuchi, the thanks of the Executive Committee are due for their cordial coöperation in this respect. The General Superintendent attended the Second Conference on Cancer in Paris as the delegate of His Majesty's Government. A report on the Conference was prepared by Dr. Bashford for the Government and published as a Parliamentary paper.

The plans of the laboratories to be provided by the Royal Colleges of Physicians and Surgeons for the Imperial Cancer Research Fund in the new Examination Hall have been carefully considered by the Pathological Subcommittee, by whom several valuable suggestions have been made. These suggestions having been adopted, it is believed that the new laboratories will be very complete and fully equal to the demands of the work. The Executive Committee have agreed to contribute towards the cost of the laboratories by payment of a premium for a definite period of occupation or by the payment of an annual rental. Professor Welsh of Sydney and Dr. Sluys of Brussels have worked during the year in our laboratories with a view to acquire a knowledge of the methods of investigation pursued there. The accumulation of material for publication has decided the committee to issue another volume of scientific reports. This volume is now in the press and will probably be ready early in the autumn. It will contain papers on: (1) Spontaneous Tumours in Mice; (2) Cancerous Ancestry and the Incidence of Cancer in Mice; (3) The Behaviour of Tumour-cells during Propagation. Its preparation has involved a considerable amount of work by the Pathological, Statistical, and Publication Subcommittees. The committee, on the recommendation of the General Superintendent, decided in December last to offer to the Council of the Royal College of Surgeons for addition to its Museum numerous specimens which have been collected by the staff since the foundation of the Fund, showing cancerous growths in animals and the experimental reproduction and prevention of the lesions of the disease. This offer was gladly accepted, and the specimens are now exhibited in the Museum of the College.

As mentioned in the last report, Dr. Magnus Haaland terminated his connexion as a member of the staff on Feb. 11th last, on taking up his new appointment as director of the Pathological Institute of Bergen. In the vacancy occasioned by Dr. Haaland's resignation Dr. Russell has been appointed second assistant and Dr. Woglom has joined the staff as third assistant. The General Superintendent has recently fulfilled a promise to send an exhibit on behalf of this fund to the British Section of the International Hygiene Exhibition of Dresden. Dr. Murray attended in Dresden to arrange the exhibit, which has proved to be of considerable interest. The following papers have been issued from our laboratories during the year: On Knowledge of Peptolytic Ferments in different Carcinomata and other Tumours. Third Contribution. (Zur Kenntnis der peptolytischen Fermente verschiedener Krebse und anderer Tumorarten.—III. Mitteilung.) Hoppe-Seyler's Zeitschrift für Physiologische Chemie, Vol. lxvi., 1910.[1] Cancer in Domesticated Animals. Annual Conference of Veterinary Officers of Health, Glasgow. *Veterinary News*. September, 1910. Spontaneous Cancer in Mice. Proceedings of the Royal Society, B., Vol. lxxxiii., 1911. The Obligation imposed upon the General Practitioner by the Development of the Experimental Investigation of Cancer. *Practitioner*, March, 1911.

At the invitation of the Norwegian Medical Society the General Superintendent gave an address in Christiania on March 8th on "The Investigations of the Imperial Cancer Research Fund." Dr. Bashford, on the invitation of the University of Birmingham, also delivered the Ingleby Lectures at Birmingham in May last, the subject being "Advance in Knowledge of Cancer." An abstract of these lectures appeared in THE LANCET, June 10th, 1911, and in the *Birmingham Medical Review*.

FREDERIC G. HALLETT, Secretary.

Report of the General Superintendent.

The preparation of an annual report on the progress of investigations directed consistently to the solution of major problems necessitates a re-survey of much ground already traversed, with the addition here and there of new facts or modifications affecting the interpretation of old ones. The reports come to be really an annual review of the position of knowledge, dependent on investigations conducted in the laboratory, but also influenced by those conducted elsewhere, either at home or abroad. The scope of the investigations carried out during the past year has been very similar to that recorded in the Eighth Annual Report; the main work carried out during the year has been the maturing and preparing for publication some of the investigations outlined in the last report. This has involved much repetition of experiments for checking and supplementing results already arrived at, in order that they might be presented in the form of the Fourth Scientific Report, which is now in the press. A feature of this year's work is the extension of experimental investigation to rabbits, in which animal a carcinoma of the mamma and a sarcoma of the subcutaneous tissue have been discovered, the latter being capable of propagation. The Fourth Scientific Report, apart from an introduction, is restricted to three papers which bear directly upon the nature of cancer, and indirectly upon the genesis of some forms of the disease. The necessity for narrowing the field of inquiry was alluded to in the First Annual Report. This object has been advanced materially by the demonstration that the relation of each malignant new growth to the affected animal is an individual one, parallel to that obtaining between the organs of the body and the organism as a whole. More precise conceptions have been obtained of the influence of heredity in place of the indefinite and contradictory views previously current. Cellular alterations bridging over the differences between normal and cancerous cells have been demonstrated to take place in growths under continuous observation and under natural conditions. Taken together these three advances indicate the direction in which further investigation can be profitably undertaken. In addition, these demonstrations are supported by most important new statistical information which has been made accessible in the last report of the Registrar-General.

Statistics.—It will be remembered that the policy pursued in regard to the statistical investigation of cancer has been to supplement the national statistics, and, if possible, to add to their utility by special inquiries, but not to endeavour to overlap or in any way to replace them. This policy has been dictated by the belief that the adequate investigation of most of the statistical features of cancer is best carried out by the Registrar-General's Staff, since the data available for such a purpose do not exist outside of the national statistical office. It has been encouraged by the willingness with which the medical superintendents of statistics have collaborated with the Imperial Cancer Research Fund in supplementing and amplifying information calculated to assist purely pathological and experimental investigations. This collaboration and coördination, which does not exist in the case of organisations for the investigation of cancer in other countries, where independent statistical inquiries have been undertaken with the voluntary assistance of the medical profession, has been of the greatest importance in England and Wales by preventing profitless overlapping and in effecting real advances in the accurate statistical knowledge of the incidence of cancer. For several reasons it had long been desired that the reports of the Registrar-General should contain detailed information on the incidence of cancer in different parts of the body, and Dr. Tatham was able to make arrangements for obtaining this information at the outset of these investigations. The application of the law of age-incidence for cancer to short-lived as well as to long-lived animals reinforced the other reasons for obtaining it, and suggested that knowledge would be advanced by more detailed information about the age-incidence of cancer in the several organs of man as distinct from its dependence on the age distribution of persons.[2] It was anticipated that the data would be of both biological and statistical value, and the facts published by Dr. Stevenson in the last report of the Registrar General illustrate that this hope has been fulfilled in several directions. The tabulation of the new data for the years 1901-09 has permitted an analysis of the figures recording the increase of deaths attributed to cancer, and bringing out the fact that the increase during this period is referable to certain anatomical regions and not to others. Thus, for males, the main increase falls on the alimentary tract, especially the stomach. The liver and gall-bladder and the skin show no, or only a slight increase. For females, the increase, although it falls mainly on the alimentary tract (stomach and intestines), affects also the mamma, while the uterus, ovary, liver and gall-bladder, rectum and skin show little or no increase. It is also of importance that the recorded mortality from cancer of the generative organs has not increased at the same rate as that for other organs, and that most of the increases affect the higher age-periods predominantly. For the first time it is fully demonstrated that it is wrong to make statements of a disquieting nature about the increase of cancer in general. In conjunction with other investigations means are also afforded of determining for parts of the body where the disease appears to be increasing, whether the increase is real or only apparent, and of ascertaining the causal factors peculiar to such parts. While it is evident that several of the differences brought out by the figures can be explained by more accurate diagnosis and by transference of the seat of the disease from the secondary to the primary situations, as illustrated, e.g., by the relation revealed between cancer of the liver and gall-bladder and the alimentary tract, this may not account fully for other features. In particular, the increase recorded for the mamma in women and the tongue in men requires further study and elucidation. Secondly, the analysis shows that the incidence is very unequally distributed among the several situations, and, indeed, that the whole curve of incidence may be different for different organs. A progressive increase up to the highest age-periods is characteristic of the face, lip, mouth, bladder, urethra, and breast only. The other organs show a distinct diminution in the highest age-periods; but it is not yet possible to determine whether this curve indicates a liability rising to a maximum followed by a diminution, or is merely the result of deaths being still ascribed to other causes in the case of cancer of internal organs in aged people. The proportion of total deaths ascribed to the ill-defined cause of old age is 65·6 per 1000 as compared with 65·7 for cancer, and it must be borne in mind that the increases recorded for cancer affect principally the higher age-periods and that the average age of the population is increasing. Sufficient has been said to indicate how important are the problems which are solved or revealed by the improvement in the details given in the national statistics. The study of the occurrence of cancer in mankind, and in domesticated animals in widely separated parts of the globe, has shown that the practice of peculiar customs (involving the subjection of particular parts of the body to chronic irritation), provokes the disease in situations and organs from which it is absent when these customs do not obtain. It is reasonable to suppose that the frequency of cancer would be diminished if such practices as the use of the kangri in Kashmir, the chewing of betel-nut, the eating of very hot rice in China, were discontinued. It is also reasonable to assume that the introduction into England of these exotic customs would greatly increase the frequency of cancer in this country. So definite is the evidence of the mediate causation of certain forms of cancer by chronic irritants that the possibility of variations in the cancer death-rate must be admitted as regards particular organs and regions of the body. The possibility of a variation of the main incidence of cancer in conformity with changes in certain customs must also be admitted. That irritation is really an important causative factor of cancer is an assumption

[1] In collaboration with the Physiological Institute of the Royal Veterinary College, Berlin.

[2] Second Scientific Report, Part I.

which is justifiable only for certain forms of cancer occurring in particular regions. The knowledge of the irritants to which different species of animals and the individual tissues of the same animal are susceptible is of very considerable importance. The acquisition of this knowledge will doubtless require extensive study, and it is advisable to approach this study in man statistically. In view of these considerations, and also because of the results of experiment, it appears advisable to have data of the incidence of cancer in persons pursuing different occupations. This matter was discussed with Dr. Tatham in 1903-04, and again discussed with Dr. Stevenson of the General Register Office, who has been so good as to explain to the Statistical Subcommittee that the new arrangements made by the Registrar-General for tabulating deaths would permit of this information being abstracted. For the purposes of comparison it will be necessary to learn not only the incidence of cancer on particular sites liable to irritation, but also the incidence of cancer on all other sites, as well as the incidence of the other causes of death in the occupations considered. This information will be embodied in the next decennial supplement to the reports of the Registrar-General. Of other statistical matters, reference may be made to the fact that over 4000 cases of cancer have now been collected from India. The figures confirm the conclusions already stated. Of interest has been a large series of cancer cases of which reports and specimens have been sent from Khartoum by Mr. Christopherson, the cases occurring in Arabs and in the natives of the Sudan and Bahr-el Ghazel remote from the influences of European civilisation. Dr. Preston Maxwell has drawn attention to a peculiarity in the incidence of cancer in China, where the men are very liable to cancer of the œsophagus, whereas in Chinese women the disease is rare or unknown. In China Dr. Preston Maxwell suggests that the difference is due to the men bolting their rice whilst it is very hot, the men being served first and the women afterwards when the rice has become cooler. Enough has been said to show that the statistical inquiries continue to add, each in its own way, to our knowledge of cancer either by revealing new facts or by giving, if not yet a true, still a more precise significance to old ones. Another form of inquiry which has been both statistical and experimental has thrown light upon the long-debated question of heredity.

Heredity.—The breeding experiments which have been in progress for many years have been alluded to in several earlier reports. They have now yielded upwards of 2000 mice of known ancestry and age. 562 females were available for a study of the influence of heredity on the development of cancer of the mamma when an analysis was made on Oct. 24th, 1910. The figures are arranged in the accompanying tables so as to bring out the ages of the mice, and the proportions which developed cancer of the breast in the two groups into which they have been segregated according to ancestry. All due precautions have been taken to avoid errors in the interpretation of the figures. The data show that heredity plays a part in the development of cancer of the breast in mice. At all age-periods the disease is more frequent when the mother, or either grandmother, or all three, had died from cancer of this organ.

TABLE I. (*Oct. 24th, 1910*). *Female Mice of Recent Cancerous Ancestry.* (*Mother, one or both grandmothers, or all three cancerous.*)

Age (months)	0-3	-6	-9	-12	-15	-18	-21	-24	Over 24.	Total.
No tumour—										
Living	—	—	9	7	6	8	7	4	6	47
Dead	—	—	49	48	39	28	22	20	18	224

The maxima occur at the same age-period in each group, being respectively 21·6 and 32·1 per cent. of the total number of animals, there being no evidence that the maximum incidence of cancer has been made to occur at a younger age in mice of recent cancerous ancestry. Without wishing to minimise unduly the important influence which heredity is thus demonstrated to have, it is necessary to warn against needless alarm or the awakening of pessimistic anticipations of the outlook on future efforts to cope with cancer. It has been sought deliberately to concentrate any tendency to the disease which may be due to heredity, and in this way to obtain mice more liable to the disease than are others. Apart from its bearing upon heredity, the obtaining of such mice was most important for furthering the experimental investigation of the genesis, nature, and should it be necessary artificial production of cancer, and for attempting to define the reasons for its apparently greater frequency in some geographical areas than in others. It will be obvious that a large field of investigation has been opened up by the segregation of mice into two groups of different liability, and it should be possible to obtain groups of animals of a still higher and a still lower liability. An effort is now being made to obtain by selection a breed of mice with diminished liability to cancer. While it is at present impossible to explain how the liability is transmitted, it can be averred with certainty that it does not consist in the inheritance of a soil more suitable for the growth of cancer in general. It is not the inheritance of a general constitutional predisposition suitable for growth, as is shown by the fact that implantation of cancer is not more successful in mice of a cancerous stock than in others. It can only be inferred, with some probability, that it is a local or circumscribed tissue predisposition, in virtue of which the mammary tissue is prone to pass from mere proliferative reaction into continuous or cancerous proliferation. Further, hereditary predisposition is only one of the factors in play, for it has been found that chronic inflammatory changes are remarkably frequent in the mammæ of female mice of the laboratory. Other factors still unrecognised may exist. It has been possible to obtain a sequence of all stages from normal tissue through mere chronic inflammation and simple hypertrophy, to adenoma and carcinoma. The manner of the occurrence and combination of these changes strongly suggest their interdependence and reference to a common cause which becomes effective in producing cancer through the variability of the normal cell as described below.

Individuality and cancer.—The study of the parallel behaviour of normal and cancer tissue both as regards absence of continued growth and the nature of the immunity reactions induced, when cancer is transferred from one animal to another of a strange species, showed that cancer had all the properties which distinguish the normal tissues of one species from those of another species. Recent experiment has carried knowledge much further. The fact that transplantable tumours grow in normal animals as well as they do in spontaneously affected animals shows that the latter do not present a soil for the growth of cancer substantially different from that presented by normal animals. When this result is contrasted with the almost invariable success of transplanting a portion of its spontaneous tumour into the animal so affected, and the almost invariable failure of implantation of any spontaneous tumour into other spontaneously affected animals, the demonstration is complete that each tumour is peculiarly and genetically related to the individual in which it arises. This conclusion is drawn from studying the growth of tumours under the different conditions just enumerated, and is supported by the results of elaborate experiments on inducing resistance or immunity to the inoculation of cancer cells under these different conditions. The results of these two lines of inquiry agree also with the fact that resistance has not been induced either with an animal's own tumour or its own normal tissue.[3] The individuality of cancer would thus appear to have been placed at last beyond all further discussion. It has long been maintained in various forms on the basis of deductions drawn from histological (microscopical) examination of the tissues at the site of the primary lesion, and from the nature of dissemination, but this interpretation of the findings has been as vehemently combated. The combination of the results arrived at by microscopical investigation and experimental study appears to terminate any need for further discussion. A long step has thus been taken in defining the direction in which the future investigation of cancer is alone likely to be profitable.

The nature of cancer.—It follows from the argument pursued in the preceding paragraphs that a closer definition of the nature of cancer will involve an analysis of the relation obtaining between the individual developing cancer and the tumour. This final analysis will be possible only on animals naturally afflicted with the disease, for, as pointed out consistently from the First Annual Report onwards, the genesis and the growth of cancer are distinct phenomena which can and ought to be separately investigated. The study of propagated cancer is only a study of its growth under natural and artificial conditions, and has only an indirect bearing upon the genesis of the disease. Hence the breeding experiments, to which allusion has already been made, acquire enhanced significance, and are already being, and will continue to be, conducted on a much more extensive scale. An adequate supply of animals of differing liability to the disease must be made available for the elucidation of problems, some of which are already suspected, while past experience makes it likely that others, as yet unsuspected, will arise. In all previous reports guarded reference has been made to the mediate relation obtaining between chronic irritation and certain forms of cancer. The indefiniteness in the way of drawing attention to the relationship is deliberate. In the first place, it is due to an effort to elucidate those forms of cancer with which irritation is most constantly associated without considering other forms in which the particular irritants concerned do not play a part. In the second place, it is due to the fact already frequently emphasised, that these irritants have nothing in common beyond their association with cancer. The varied investigations of the past nine years have added a knowledge of new forms of irritation. It has become more and more evident that irritation, effective in one case, may be, and often is, quite ineffective in another. The experimental aspect of the comparative investigation of cancer has met with much adverse criticism largely because of the necessity for reproducing experimentally all the natural lesions of the disease, and then utilising this procedure to devise methods to prevent them, as well as from the necessity for cultivating the cancer cell in order that a constant supply may be available for a variety of purposes. This supply can most satisfactorily be maintained by growth in living animals, the application to tumour cells of Ross Harrison's method of cultivating normal tissues in coagulated plasma by Burrows and Carrel being still impracticable as a routine method of

[3] In last year's annual report it was stated that an animal could be immunised against the transplantation of a tumour from another animal by means of one of its own tissues. More extended investigation has shown that this result is not invariably obtained.

continuous propagation. Ever since the beginning of these investigations it has been maintained that the mere cultivation of cancer had important, if only indirect, bearings upon its nature and genesis. Thirty-five of the tumour-strains have now been growing for over three years—i.e., for longer than a mouse lives—while 50 other strains have been grown for extended periods. The one feature all these tumour-strains have in common is the power of continuous growth which they possess, in spite of the most divergent structure and of extremes in the rate of growth varying from an almost explosive rapidity to one much inferior to that of embryonic tissue, as determined by weighing experiments. It can be shown that there is a constancy in the behaviour of a tumour-strain and a variability which is individual. The variations which occur are similar to those which distinguish the 85 different strains from one another. They are not mainly induced by the environment but arise spontaneously; otherwise all strains would approach a common type, which they do not. The demonstration of the occurrence of these variations under artificial conditions permits of the inference that they could also occur under natural conditions, and yields objective evidence of the validity of the conclusion that the cancer cell is a biological modification of the normal cell endowed with many inherent properties of the latter. The objection at once suggests itself that these variations during prolonged propagation are secondary, and do not necessarily indicate corresponding primary changes as responsible for genesis; but this objection cannot be maintained against the facts that the potentiality for variation has been demonstrated, as has also the tenacity with which the several varieties are adhered to. It has been ascertained that every fresh transplantation effects a disturbance of the cancer cells. They are thrown into a state equivalent to regeneration from which they tend to recover, as analogous as possible to reactive proliferation when naturally occurring. Hence the features observed under artifical propagation throw suggestive light upon the nature of cancer and its genesis in those cases in which a prolonged phase of reactive proliferation has intervened between the first response to irritants and the development of cancer.

Immunity and therapeutic investigations.—Apart from the investigations in which the reactions of immunity have been employed to elucidate the nature of cancer, numerous experiments bearing upon the possibilities of treatment have continued to be made. The onset, rise, fall, and disappearance of immunity as induced by the inoculation of normal and cancerous tissue has been accurately defined in parallel experiments. The distinctions and similarities in the immunising powers of different tumours, especially of sarcoma as distinct from carcinoma, have been extensively studied. The dissemination of cancer has been studied experimentally both by injecting cancer-cells directly into the blood-stream and by implanting them in internal organs. It has been found possible to produce the lesions of dissemination in these ways both in the absence and in the presence of a primary growth, and, what is more important also, to prevent them. Since every procedure found efficacious to modify in any degree the growth of transplanted cancer has been tested on mice naturally affected with the disease it is needless to enter into details, more especially since problems difficult of solution in the mouse, because of its small size and the short duration of its life, can now be studied under the more favourable circumstances obtaining in the rabbit. As pointed out in previous reports, nothing but harm can result from the premature application to the treatment of the human subject of methods found to modify the growth of propagated cancer in animals. In order to emphasise still more strongly this warning it may be stated that the methods which induce an *active* immunity to propagated cancer have been tested on 33 mice with natural cancer, and have given no evidence of powers either to hinder growth and dissemination, or to prevent recurrence of spontaneous cancer after surgical removal. These methods have also been found to be of no avail in preventing the successful inoculation of an animal with its own tumour; and they have their practical application at present only in the elucidation of the properties of cancer cells. The successful treatment of animals bearing propagated cancer by means employed to induce *passive* immunity has been described by other investigators. Some of these methods have been tested in the laboratory, but have not yielded positive results. It becomes increasingly evident that the therapeutical treatment of cancer is not to be sought for along these lines. A considerable number of cases of natural healing of spontaneous malignant new growths has now been observed in mice affected with spontaneous cancer. The changes leading to natural cure appear to depend, as in propagated cancer, on an altered condition of the cell and its contents, rather than on an alteration in the general condition or constitution of the affected animal. Means must be devised for elucidating the nature of the change in the cell before curative measures can be discovered.

Since these investigations were first contemplated by those responsible for their inauguration, the provisions made for the investigation of cancer have greatly altered in this country. Whereas nine years ago, apart from special provision for treatment being supplied by a number of hospitals, there existed for the investigation of the disease only one other laboratory in addition to the imperial organisation contemplated by the founders of this Fund, to-day a number of other laboratories exist throughout the country, both in London and the provinces; England and Scotland are now provided with a greater number than any other country in comparison with their size and population. Whenever an opportunity has occurred of furthering the particular investigations upon which these institutions have been engaged, assistance has been rendered by supplying material from the laboratory and by the Imperial Cancer Research Fund in many other ways. The responsibilities thrown upon the workers of the Imperial Cancer Research Fund are not diminished, but rather increased, by the multiplication of institutions engaged in the investigation of cancer.

ERNEST F. BASHFORD, M.D.,
General Superintendent of Research and
Director of the Laboratories.

Report of the Honorary Treasurer for the Year ending June 24th, 1911.

The income from investments for the year 1910–1911 was £4584 10*s.* 6*d.* The expenditure for the same period amounted to £5478 2*s.* 8*d.* A contribution from an anonymous donor of £1000 has been received for the specific purpose of equipping a bio-chemical laboratory. Legacies to the amount of £1936 7*s.* 4*d.* have been added to the Fund during the year, and £850 11*s.* 6*d.* have been received in subscriptions from 97 subscribers of sums varying from £100 to 5*s.* The excess of expenditure over income during the last year amounted to £893 12*s.* 2*d.* It is very considerably less than in any previous year, except in the first year of the existence of the Fund. During the year just ended there has been no exceptional or unusually heavy expenditure and the research work of the Fund has been carried on, as formerly, in premises provided, rent and taxes free, by the two Royal Colleges. This, however, is the last year that the Fund can expect to benefit by these special advantages. When the next report is made to the General Committee the work of the Fund will have been transferred to the new Examination Hall which is being erected by the Royal Colleges in Queen-square, Bloomsbury, and it is expected that either a premium for a definite term of years will have to be paid down or that the payment of an annual rent will begin to appear in the expenditure side of the balance-sheet. Another large volume of scientific reports is now in course of passing through the press, and this, besides having involved a very considerable amount of work on the part of the director and his staff and the several subcommittees, will make a very heavy demand upon the ensuing year's resources.

The general superintendent in his report has referred to the new responsibilities which are being thrown on his staff by the increase in the number of workers engaged in the investigation of cancer in other centres. Many of these centres have naturally looked to the Imperial Cancer Research Fund to assist them, but the provision of this assistance adds greatly to the mere routine work conducted in the laboratories. Owing to the advance in our knowledge much of what was originally investigation of prime importance has now become routine work and could well be deputed to a subordinate staff trained for the purpose. The provision of such a staff would set free the more highly trained men capable of original research, on whom we must rely to maintain the scientific reputation which the Fund has obtained. In order that this much-desired end may be achieved, it is essential that the Fund should have at its disposal a considerably augmented income. Moreover, a reconsideration of the scale of remuneration of the superior staff is essential if the Fund is to maintain a position commensurate with the duties and responsibilities of a truly imperial organisation. For these reasons it is most undesirable that the Fund should have to be constantly drawing upon its capital, and once more I must call attention to the pressing need for such a substantial increase in the endowment as will provide an income sufficient to defray all the ordinary and, from time to time, extraordinary expenses of the work.

HENRY MORRIS, Honorary Treasurer.

Sir HENRY MORRIS, in seconding the adoption of the report, uttered a warning against misapprehending the favourable report of the treasurer. It was true that this year the expenditure had exceeded the funded income by only £893, whereas on some prior occasions the excess had been as much as £2000. But this year there had been no unusual expenses. Next year, however, the large amount expended on the Scientific Report now in the press would make itself felt. Notwithstanding that in the nine years that had elapsed since the foundation of this Fund many new bodies and laboratories for cancer research had come into being both here and abroad, the value of this Research Fund was shown in three ways: by the great number of distinguished investigators who came from all parts of Europe, America, and from Japan, to study the methods of research in progress in that laboratory; by the fact that the director of the laboratory had been called on by leading scientific bodies in Paris, Berlin, Heidelberg, Toronto, Christiania, Utrecht, and Budapest, and elsewhere, not to mention many English research centres, to deliver addresses before them explanatory of the methods used; and by the fact that a committee, not confined to the Royal College of Surgeons of England, but assisted by the advice of other centres of investigation in Europe and America, had conferred upon thei director, Dr. Bashford, the Walker prize for the best original work done during the past five years in any country towards advancing our knowledge of cancer. Sir Henry Morris urged the necessity for reviewing the scale of remuneration, because it was essential that the Fund should be able to retain the best and most highly trained workers, and there was arising a demand for workers trained in that laboratory for other places at higher salaries.

The resolution was carried unanimously.

The DUKE of BEDFORD, from the chair, then moved a vote of thanks to the chairman, members of the Executive Committee, the sub-committees, the honorary treasurer, and others who had assisted in the work of the Fund during the past year. These gentlemen, he said, were mainly representatives of various scientific bodies who ungrudgingly gave their time and skill to the consideration of the problems continually brought before them by Dr. Bashford and his staff. Scrupulous care was exercised by them to avoid unguarded statements that might unduly exalt or depress the public hopes. They owed thanks also to Dr. Stevenson, of the Registrar-General's office, through whose cordial coöperation the investigation of the distribution of cancer was rendered possible, while profitable lines of investigation were being indicated by the differentiation of the various groups of the disease which affected the different parts of the body in different ways. Next year the Fund would move to the new laboratories, now being erected over the new Examination Hall of the Royal Colleges. The

improved accommodation, planning, and equipment justified the Executive Committee in its agreement to contribute in the form of premium or rent for these laboratories, and he hoped that additional public support would enable them to meet this tax without encroaching on the capital of the trust. Progress was being made, but there would be much expenditure in time and money before definite results could be obtained, and once more they had to ask their supporters to exercise the virtue of patience.

Sir RICHARD DOUGLAS POWELL seconded the motion, which was unanimously adopted.

Sir HENRY BUTLIN moved, and Sir JOHN MCFADYEAN seconded, the nomination for re-election by the Royal Colleges of Physicians of London and Surgeons of England of Sir William Church as a member of the Executive Committee. This also was carried.

Sir THOMAS BARLOW proposed a vote of thanks to the Duke of Bedford for presiding, which was seconded by Sir JOHN TWEEDY and unanimously carried.

BRITISH PHARMACEUTICAL CONFERENCE.

Presidential Address.

THE forty-eighth annual meeting of the British Pharmaceutical Conference was opened at the Municipal College, Portsmouth, on July 25th, when, after an address of welcome had been given on behalf of the municipality, Mr. W. F. WELLS (Dublin) delivered his presidential address, which dealt mainly with the laws relating to the sale of poisons in the United Kingdom. He showed that the one idea running through the various Pharmacy Acts was the protection and convenience of the public, the public health and the lives of the people being considered of paramount importance. The essential difference between the pharmacy laws of the United Kingdom and those of France is that the French laws give the pharmacist a definite place in the community, specific services to perform for the community, and ensure that none shall poach upon the preserves fenced by these laws. In Germany the practice of pharmacy is strictly confined to qualified persons, and a custom exists there which is unknown either here or in France of strictly limiting the number of pharmacies, each pharmacy throughout the Empire being licensed by the State. The consequence is that in Germany a pharmacist cannot start business until a vacancy for a pharmacy occurs and he obtains or purchases the concession to carry on the business of an old-established pharmacy, or to open a new one where the growth of the population warrants the State granting a new concession. After further demonstrating the superiority of the German and French systems over the British and Irish, Mr. Wells asked, "Might not the British Government with advantage take a lesson from our French and German neighbours, and, when importing German-made insurance schemes, go a little further and include an order for a few pharmacy laws 'made in Germany'?" Mr. Wells had a word to say concerning the supply of drugs to Irish boards of guardians. In Ireland the Local Government Board compel the guardians of unions to accept the lowest tender, and the result of this may best be shown by quoting the President's words. "What becomes," he asked, "of the tons of damaged and useless drugs that from time to time are placed on the market? Much of the stuff which is unsaleable in the British drug market is, I believe, sent abroad, and yet finds it way back again, having been either 'cooked' or redressed, to Great Britain and Ireland for consumption. Who is responsible for this state of affairs? The answer is the boards of guardians, governors of institutions, and the public who insist on buying medicines at competitive prices at which we know they cannot be produced. It appears to me a cruel thing—I might go even further and say a criminal thing—for those who have in their hands the care of the sick poor in public institutions to purchase the supplies of medicines, putting price first, and too often without regard to quality or therapeutic value, the lowest tender being the one standard of merit." As to the National Insurance Bill, the President had little to say except that if passed in its present form it would certainly injure many a pharmacist.

Papers read in the Science Section.

The reading of papers in the Science Section was begun at the conclusion of the Presidential address and continued on the following day. There were in all 20 papers, some of which were brief notes on subjects of purely pharmaceutical interest. Several of the papers were of some importance to medical practitioners, as, for instance, the communication by Mr. R. R. BENNETT, B.Sc., F.I.C., on a Suggested Standard for Thyroideum Siccum. There is a widespread belief among clinicians that the commercial thyroid preparations vary considerably in their degree of physiological activity, but at the present time there is no officially recognised standardisation process. The agreement among the majority of pharmacologists that the activity of thyroid is directly proportional to, and dependent upon, the combined iodine present appears to, render it urgently desirable that an iodine standard should be fixed, especially in view of the wide variations in the iodine content of commercial samples of thyroideum siccum. Specimens of this product from four of the leading manufacturers have been examined recently, and the combined iodine present has been found to vary in amount from 0·315 per cent. to 0·038 per cent. The percentage of iodine in dry thyroid obtained direct from the slaughter-house has also been determined, the glands having been treated in accordance with the directions in the British Pharmacopœia; the iodine present in these powders has been found to vary from 0·21 per cent. to 0·096 per cent., the average value being 0·158 per cent. Mr. Bennett's figures confirm those obtained by previous investigators, and in his opinion these figures indicate that an iodine standard of 0·15 per cent. might be adopted for thyroideum siccum without in any way unduly harassing the manufacturer.

Mr. H. DRANE, B.Sc., F.I.C., in a paper on Extract of Indian Hemp, drew attention to the variability of this extract as supplied by manufacturers. The pharmacopœial preparation is unsatisfactory, being composed of two constituents, a green resin and brown water-soluble extractive matter, which show a tendency to separate, and, moreover, it is by no means completely soluble in alcohol, which makes the preparation of the tincture troublesome and messy. Therefore a demand has arisen for an extract soluble in alcohol; hence the reason for the predominance of non-official extracts. There is little doubt that the resinous portion of the extract contains the active principle, and extracts which are practically pure resin may be expected to be therapeutically more active as well as pharmaceutically more elegant than other extracts. To obtain such an extract the method suggested by Mr. Drane was simply to wash away the brown extractives with warm water after the spirit had been distilled off in the same way as resin of jalap and resin of scammony are prepared. He suggested that this method should be adopted by the Pharmacopœia, so that the present unsatisfactory state of affairs might be altered.

In a paper on the Supposed Loss of Morphine in the Preparation of Tincture of Opium, Mr. E. H. FARR, F.C.S., and Mr. R. WRIGHT, F.C.S., demonstrated that when the official methods are followed throughout there is always a loss. In seven samples of opium worked upon this varied between the limits of 0·8 per cent. and 9·0 per cent. of the whole, with an average for the whole series of 4·78 per cent. In the light of these results it is evident that, notwithstanding the amount of careful thought and experimental work which has been devoted to the subject of opium assay, there is still room for a thorough and systematic review of the whole subject. If the principles of the process had been radically unsound, the authors would have expected to find the deficiency of morphine to be more constant and regular than is the case. The loss appears to them to be due more probably to the occlusion of the alkaloid, rendering its complete extraction by water or alcohol a matter of practical impossibility, or to some other factor which has hitherto escaped recognition.

A paper of particular interest to medical practitioners was read by Mr. F. W. F. ARNAUD, F.I.C., on the Composition of Diabetic Foods. The term diabetic food embraces a very wide class of food products, but in this communication gluten bread and flours only were dealt with. The majority of the almond, milk protein, and soya bean, &c., preparations are known to contain less than 10 per cent. of starch, dextrin, and sugar together. Mr. Arnaud examined 12 different samples of gluten bread and flours, the product of seven manufacturers, and the conclusion he came to was that the products of one manufacturer only were satisfactory. He described the method of analysis adopted and tabulated the results. Drawing attention to the advertisement matter

of some of the firms in question, he said that one firm submitted that its products were more nutritious than any other preparation of the kind; again, a statement advertised very generally was to the effect that the starch present in the foods had been altered, so that it could be digested and assimilated by the diabetic subject. But Mr. Arnaud cannot confirm the statement that the starch is appreciably altered either by the qualitative iodine test or the microscope. A sample of an expensive diabetic food was found to consist of ordinary flour which had merely been heated.

In a note on Linimentum Ammoniæ, Mr. F. H. ALCOCK, F.I.C., suggested an improved formula for this preparation. When made according to the official process the liniment sometimes becomes solid on keeping. His suggested formula was as follows: almond oil, 3 fluid ounces; olive oil, 8 fluid ounces; strong solution of ammonia (0 880), 1 fluid ounce. The product has not such a good appearance as the fresh official preparation, but is very effectual. He did not know why the expensive almond oil was introduced into the official formula, and thought that olive oil alone might be used with his suggested formula.

Mr. D. B. DOTT, F.R.S.E., in a note on Spirit of Nitrous Ether, said that under practical conditions of dispensing it was difficult to avoid the volatilisation of the ethyl nitrite. He therefore proposed that no spirit of nitrous ether should be kept in stock at all. There would be two solutions, like Fehling No. 1 and No. 2, which would be mixed when dispensing, using ½ fluid drachm of sodium nitrite solution with 7½ fluid drachms of alcohol acidified with lactic acid. The proposal was made in view of the forthcoming Pharmacopœia. Mr. Dott also read short notes on Strychnine Hypophosphite and Arsenates of Strychnine.

In a note on Solution of Sodium Ethylate Mr. H. FINNEMORE, B.Sc., said it usually happened when this solution was required for use the "stock" was dark in colour; although its medicinal properties are not affected by this colouration, the user is apt to assume that deterioration has accompanied the change. A sample of solution of sodium methylate showed no trace of discolouration after two years. Mr. Finnemore also (with Mr. G. E. TOWN) contributed a note on Bartsia Odontites.

A communication on Podophyllum Emodi was contributed by Mr. J. C. UMNEY, F.C.S., who referred to the second report of the Indigenous Drugs Committee of India, which dealt with Podophyllum emodi amongst other drugs. Some medical opinions recorded in that committee's report indicated that the purgative action of P. emodi resin was better than that of podophyllum resin (B.P.), as the drug did not produce griping; whilst other medical opinions were that it was about equal in value to the pharmacopœial resin. At the request of the Indian Drugs Committee Mr. Umney conducted a series of experiments upon the drug, collected under different conditions and at different seasons. He found that the Indian rhizome collected after flowering was at least twice as rich in podophyllotoxin as the American rhizome.

The titles of other papers were as follows: "An Experiment in Peppermint Culture," by Mr. J. H. HENDERSON, in which it was shown that the oil yield of peppermint grown in the shade was less than a quarter of the yield of ordinary plants; "Note on the Constitution of Commercial Bismuth Subchloride," by Mr. J. B. P. HARRISON, F.I.C; "White Precipitate and the Analysis of White Precipitate Ointment," by Mr. G. D. ELSDON, B.Sc.; "Note on Spirit of Sal Volatile," by Mr. E. W. POLLARD, B.Sc.; and "The Moisture and Ash Contents of Medicinal Extracts," by Mr. K. C. ALLEN and Mr. T. BREWIS, F.I.C.

In the Practice Section there were discussions on Secret and Proprietary Medicines, Pharmaceutical Education, and the National Insurance Scheme.

DEATH FROM SALVARSAN.—At the Hackney coroner's court on July 19th Dr. W. Wynn Westcott held an inquest with reference to the death of a man, aged 47 years, who died from the effects of taking salvarsan, or "606." Dr. George Dorner, medical officer of the German Hospital, said the deceased suffered from locomotor ataxy. His condition was serious. He was treated with salvarsan and received an injection of 0·6 gramme, about 7 grains being the dose. After the treatment he became worse and died. The jury returned a verdict that the man died as a result of the injection of salvarsan properly used.

METROPOLITAN HOSPITAL SUNDAY FUND.

THE following are among the amounts received at the Mansion House up to July 22nd (total available for distribution, £45,700):—

	£	s.	d.
St. Mary Abbots (total)	422	0	0
West London Synagogue	318	0	0
St. Paul's, Knightsbridge	280	0	0
Kensington Parish Church	274	0	0
Great Synagogue, Aldgate	237	0	0
Westminster Abbey	203	0	0
Holy Trinity, Kensington Gore	175	0	0
Hampstead Synagogue	152	0	0
St. Paul's, Hampstead	138	0	0
Central Synagogue	124	0	0

SEVENTEENTH INTERNATIONAL CONGRESS OF MEDICINE (LONDON, 1913).

MEETING OF ORGANISING COMMITTEE.

A MEETING of the Organising Committee was held on Friday, July 14th, at the Royal College of Physicians of London, Sir THOMAS BARLOW, the President, being in the chair.

There were present, among others, Sir Dyce Duckworth, Dr. F. W. Pavy, Sir William Bennett, Sir William Allchin, Sir William Osler, Dr. Norman Moore, Professor G. Sims Woodhead, Sir David Ferrier, Sir Malcolm Morris, Sir R Havelock Charles, Sir David Bruce, Dr. Squire Sprigge, Mr. G. H. Makins, Dr. W. P. Herringham, Dr. A. E. Garrod, Mr. C. T. Dent, Dr. T. D. Acland, Dr. Herbert Spencer, Sir A. Pearce Gould, Sir Watson Cheyne, Sir Shirley Murphy, Dr. Frederick Taylor, and Dr. Dudley Buxton.

The minutes of the last meeting, as published in THE LANCET and *British Medical Journal* of April 8th, 1911, were confirmed.

Letters of regret were read from 20 members of the committee who were unable to attend.

The report of the Executive Committee was adopted as follows:—

(1) That the printing of the Transactions of the Congress be entrusted to the Oxford Press; (2) that the Royal Albert Hall be engaged for the week of the Congress, to serve as post office, bureau, and site for the exhibition of medical appliances; and (3) that the arrangements to be made for carrying out the exhibition of medical appliances, in accordance with the resolution of the Organising Committee, be left in the hands of the Finance Committee, with power to act and report to the Executive Committee.

The HONORARY GENERAL SECRETARY (Dr. W. P. Herringham) reported that the regulations proposed at the last meeting of the Organising Committee had been laid before the Permanent Commission, and had been, with slight modifications, adopted.

The question arose as to the rules which should be

followed in sending official invitations. The matter was left in the hands of the officers for report to the Organising Committee.

The PRESIDENT then moved :—

1. That it is desirable that the staffs of sections should include members from the colonies.

This was unanimously approved.

2. That the secretary should be instructed to communicate with (*a*) the President and Secretary of the Canadian National Committee for International Medical Congresses; (*b*) the President of the Australasian Medical Congress; and (*c*) the officers of the South African branch of the British Medical Association, asking them to nominate such of their members as they may think fitted by their scientific eminence to serve on the staff of such sections.

This resolution was unanimously approved.

The PRESIDENT then submitted the list of the officers of Congress and of the staff of such sections as were already completed. This was ratified by the committee.

Further names will be added in accordance with the resolutions above.

The committee then adjourned.

CENTRAL MIDWIVES BOARD.

A MEETING of the Central Midwives Board was held at Caxton House, Westminster, on July 20th, with Sir FRANCIS CHAMPNEYS in the chair.

Dr. G. E. HERMAN moved :—

That it is expedient to act upon the following resolution: "A midwife will be deemed to have discharged the duty imposed upon her by Rule E, 20 (5) if, after having filled up the form of sending for medical help and handed it to the parent or friend, she advises the parents either to: (*a*) ask a registered medical practitioner to come to the child; (*b*) send the child to a registered medical practitioner; or (*c*) send the child to a hospital, according to the circumstances of each case."

The rule referred to provides that medical help must be sent for "in the case of the child, when there is any abnormality or complication, such as injuries received during birth, any malformation or deformity in a child that seems likely to live, dangerous feebleness, inflammation of, or discharge from, the eyes, however slight, serious skin eruptions, inflammation about the navel."

The CHAIRMAN said that at a recent penal meeting of the Board he was asked if the midwife was complying with the rules if she sent a child to the doctor. His answer was that she was not, but thinking it over he came to the conclusion that the midwife was complying with the rules. In Liverpool, for instance, there was a good eye hospital, and in the case of ophthalmia neonatorum he thought a midwife would be doing right in sending the child to such a hospital. The midwife must, however, not fail to notify the local supervising authority, and to fill up the form for summoning medical help. He desired the Board to note that his remarks must be taken as information for the Board, and not in support of the resolution proposed by Dr. Herman.

Mr. PARKER YOUNG said that the midwife might get into difficulties if she sent a child to the doctor instead of having the child first seen by a doctor and then acting on the advice given.

After the CHAIRMAN had pointed out that in the circumstances the child's interests were safeguarded, Dr. HERMAN agreed to withdraw his motion.

A letter was considered from Dr. Comyns Berkeley, obstetric physician, Middlesex Hospital, on behalf of the weekly board of the hospital with regard to a complaint made by a certified midwife of the inadequacy of the training given at the hospital. The further consideration of the matter was adjourned in order to afford an opportunity to members of the Board to visit the Middlesex Hospital and observe the methods of training adopted at that institution.

A letter was considered from the clerk of the Notts county council as to the difficulty experienced in securing the conviction of uncertified women for practising contrary to the provisions of Section 1 (2) of the Midwives Act, 1902. The Board decided it be suggested to the local supervising authority: (*a*) That an opportunity be taken of appealing to the High Court from any decision of a Petty Sessional Court holding as a matter of law that, in the absence of proof by the prosecution that the uncertified woman attending a midwifery case has been engaged beforehand, the case becomes one of emergency within the meaning of Section 1 (2) of the Midwives Act, 1902; (*b*) that the local supervising authority should itself report direct to the General Medical Council any case in which, in their opinion, a medical practitioner has been guilty of "covering."

A letter was considered from the town clerk of Sheffield as to the Board's procedure on the citation of midwives against whom *primâ-facie* cases have been found by local supervising authorities. The Board decided that the town clerk of Sheffield be informed that the meetings of the Board are open to representatives of the press who have received permission to attend, and that the citation of women against whom local supervising authorities have found *primâ-facie* cases of malpractice, negligence, or misconduct is a part of the Board's proceedings; that the responsibility of publishing any particular item of business transacted at the meeting rests with the press, and that the Board is not prepared to alter its procedure nor to argue the case further.

The Board had under consideration the National Insurance Bill, so far as it affects the practice of midwives, and adopted the following memorandum embodying the views of the Board on the National Insurance Bill :—

The Board and the National Insurance Bill.

The following is the memorandum to be submitted to the Chancellor of the Exchequer by the Central Midwives Board :—

The Midwives Act of 1902 was passed in the interests of the mothers and infants of England; this Act recognises midwives as an important body directly concerned with the safety of pregnant, parturient, and lying-in women and their infants. The results of their work during nearly ten years past are shown in the reduced maternal mortality as appears from the statistics of the Registrar-General.

In the Insurance Bill now before Parliament the midwife is ignored. The Central Midwives Board urges that this position, which it can hardly believe is intentional, should be so modified in the Bill that free choice should be given to mothers whether they wish to be attended by a medical practitioner or by a midwife. It is desirable that the position of midwives under the Bill should be recognised and defined, and their duties in respect of maternity benefits distinguished from those of the medical profession.

In our opinion it would be in the interests of the public health that a representative of the Central Midwives Board, as a statutory body, should be upon the Advisory Committee (Clause 42); also that midwives should be represented upon Local Health Committees (Clause 43 (5)). It would be advantageous that any rules or regulations of a general character relating to maternity benefits should be submitted to the Central Midwives Board for consideration, this body having been constituted the authority in charge of the regulation of the practice of midwives and having a wide experience thereon.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns 8144 births and 3751 deaths were registered during the week ending July 22nd. The revised estimate of the population of these towns in the middle of this year is 16,157,797 persons. The annual rate of mortality in these towns, calculated on this revised estimate, which had been equal to 11·7, 12·0, and 11·8 per 1000 in the three preceding weeks, rose again to 12·1 in the week under notice. During the first three weeks of the current quarter the annual death-rate in these towns averaged 12·0 per 1000, while in London during the same period the mean annual death-rate did not exceed 11·2 per 1000. The recorded annual death-rates in the 77 towns during last week ranged from 3·2 in Burton-on-Trent, 4·5 in Devonport, 4·9 in Hornsey, and 5·1 in Smethwick, to 16·8 in West Bromwich and in Tynemouth, 17·3 in Liverpool, 18·6 in Swansea, and 19·5 in Dewsbury. The 3751 deaths from all causes in the 77 towns last week showed an increase of 101 upon the number in the previous week, and included 423 which were referred to the principal epidemic diseases, against 284 and 324 in the two preceding weeks. Of these 423 deaths 236 resulted from infantile diarrhœa, 62 from measles, 52 from whooping-cough, 40 from diphtheria, 22 from scarlet fever, and 11 from enteric fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases was equal to 1·4 per 1000, against 0·9 and 1·0 in the two preceding weeks. The deaths of infants under two years of age attributed to diarrhœal diseases in the 77 towns, which had increased from 70 to 136 in the three previous weeks, further rose last week to 236, and caused the highest annual rates of 2·7 in Liverpool and in St. Helens, 2·9 in Dewsbury, 3·0 in West Bromwich and in Bootle, and 3·6 in Birkenhead. The 62 fatal cases of measles showed a further decline from the numbers in the 19 preceding weeks, and included 23 in London and its

suburban districts, 11 in Manchester, and 3 each in Nottingham, Salford, and Newcastle-on-Tyne. The deaths referred to whooping-cough, which had declined from 81 to 43 in the six preceding weeks, rose to 52 last week, and included 12 in London and its suburban districts, and 5 in Manchester. The fatal cases of diphtheria, which had increased from 21 to 45 in the four previous weeks, declined last week to 40; 15 occurred in London and its suburban districts, 4 in Portsmouth, and 3 in Liverpool. The 22 deaths from scarlet fever showed an increase of 3 upon the number in each of the two previous weeks, and included 6 in London, 3 in Liverpool, and 2 each in Birmingham, Preston, and Leeds. The 11 deaths from enteric fever, of which 2 occurred in Birmingham, were one less than the number recorded in the preceding week. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had steadily increased from 982 to 1345 in the 14 preceding weeks, had further increased to 1358 on Saturday last; 199 new cases of this disease were admitted to these hospitals during the week under notice, against 191 and 204 in the two previous weeks. These hospitals also contained, at the end of last week, 822 cases of diphtheria, 354 of measles, 287 of whooping-cough, and 47 of enteric fever, but not one of small-pox. The 985 deaths from all causes in London last week were 3 in excess of the number recorded in the previous week, and included 113 which were referred to diseases of the respiratory system, against 102 and 119 in the two previous weeks. The deaths attributed to different forms of violence in the 77 towns, which had been 155 and 194 in the two preceding weeks, were 188 last week, and 354 inquest cases were registered. The causes of 32, or 0·9 per cent., of the deaths registered in the 77 towns during the week under notice were not certified either by a registered medical practitioner or by a coroner. All the causes of death during last week were duly certified in Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Nottingham, Portsmouth, Salford, and in 52 other smaller towns; the 32 uncertified causes of death in the 77 towns last week included 7 in Birmingham, 5 in Manchester, and 2 each in London, Liverpool, Warrington, Bury, and Sheffield.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns, having an estimated population of 1,710,291 persons in the middle of this year, 838 births and 457 deaths were registered during the week ending July 22nd. The annual rate of mortality in these towns, which had increased from 13·3 to 14·9 per 1000 in the four preceding weeks, declined last week to 13·9. During the first three weeks of the current quarter the annual death-rate in these Scotch towns averaged 14·5, and was 2·5 per 1000 above the mean rate during the same period in the large English towns. The annual death-rate during last week in the eight Scotch towns ranged from 8·6 and 10·2 in Paisley and Aberdeen to 15·9 in Glasgow and 17·4 in Perth. The 457 deaths from all causes in the eight towns last week showed a decrease of 31 from the number in the previous week, and included 63 which were referred to the principal epidemic diseases, against 50 and 57 in the two previous weeks; of these 63 deaths, 28 resulted from diarrhœa, 17 from whooping-cough, 9 from measles, 4 from scarlet fever, 3 from diphtheria, and 2 from enteric fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases in the eight towns last week was equal to 1·9 per 1000; the mean rate last week from the same diseases in the 77 English towns did not exceed 1·4 per 1000. The deaths from diarrhœa, which had been 14 and 18 in the two preceding weeks, further rose last week to 28, and included 23 of infants under two years of age; 18 deaths occurred in Glasgow, 5 in Edinburgh, and 2 in Greenock. The fatal cases of whooping-cough, which had been 12 and 23 in the two previous weeks, declined last week to 17, of which 10 were recorded in Glasgow, 3 in Edinburgh, and 2 in Dundee. The 9 deaths attributed to measles were 3 in excess of the number in the previous week, and included 5 in Glasgow and 3 in Edinburgh. Three of the 4 fatal cases of scarlet fever, 2 of the 3 deaths from diphtheria, and the 2 deaths from enteric fever were registered in Glasgow. The deaths referred to diseases of the respiratory system in the eight towns, which had been 56 and 47 in the two preceding weeks, rose again to 51 in the week under notice, and were 1 in excess of the number in the corresponding week of last year. Of the 457 deaths from all causes in the eight towns last week, 171, or 37 per cent., were recorded in public institutions, and 28 were attributed to different forms of violence. The causes of 14, or 3·1 per cent., of the deaths in the eight towns last week were not certified; in the 77 English towns the proportion of uncertified causes of death during the week did not exceed 0·9 per cent.

HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,149,495 persons in the middle of this year, 767 births and 371 deaths were registered during the week ending July 22nd. The annual rate of mortality in these towns, which had been equal to 14·2 and 16·7 per 1000 in the two preceding weeks, further rose to 16·8 in the week under notice. During the first three weeks of the current quarter the annual death-rate in these Irish towns averaged 15·9 per 1000; in the 77 English towns the mean annual death-rate during the same period did not exceed 12·0, while in the eight Scotch towns it equalled 14·5 per 1000. The annual death-rate during the week under notice in the 22 Irish towns was equal to 19·8 in Dublin (against 11·4 in London), 16·3 in Belfast, 12·9 in Cork, 19·2 in Londonderry, 20·4 in Limerick, and 19·0 in Waterford; in the 16 smallest of these Irish towns the mean annual death-rate last week did not exceed 11·3 per 1000. The 371 deaths from all causes in the 22 towns last week showed an increase of 2 upon the number in the preceding week, and included 53 which were referred to the principal epidemic diseases, against 22 and 35 in the two previous weeks; these 53 deaths were equal to an annual rate of 2·4 per 1000, exceeding the mean rate from the same diseases in the 77 English towns by 1·0. These 53 deaths in the Irish towns last week from the principal epidemic diseases included 36 from infantile diarrhœa, 6 from whooping-cough, 4 from measles, 4 from diphtheria, and 3 from enteric fever, but not one from small-pox or from scarlet fever. The deaths attributed to diarrhœa, which had been 8 and 15 in the two previous weeks, further rose last week to 36; 18 deaths occurred in Belfast, 11 in Dublin, 3 in Limerick, and 2 in Londonderry. The 6 fatal cases of whooping-cough were 4 in excess of the number in the preceding week, and included 4 deaths in Dublin. Of the 4 deaths from diphtheria, which were equal to the number returned in the previous week, 2 were registered in Dublin and 2 in Belfast. Three of the 4 fatal cases of measles, and 2 of the 3 deaths from enteric fever were recorded in Dublin. The deaths referred to diseases of the respiratory system in the 22 towns, which had been 46 and 52 in the two previous weeks, declined last week to 40. Of the 371 deaths from all causes in the 22 towns last week, 112, or 30 per cent., were recorded in public institutions, and 10 were referred to different forms of violence. The causes of 14, or 3·8 per cent., of the deaths registered in the 22 towns last week were not certified either by a registered medical practitioner or by a coroner after inquest; the proportion of uncertified causes of death during the week under notice did not exceed 0·9 per cent. in the 77 large English towns, and was equal to 3·1 per cent. in the eight principal Scotch towns.

VITAL STATISTICS OF LONDON DURING JUNE, 1911.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 4·4 per 1000 of the population, estimated from the unrevised returns of the recent Census to be 4,522,628 persons in the middle of the year. In the three preceding months the rates were 4·3, 4·1, and 4·3 per 1000 respectively. The lowest rates last month were recorded in Paddington, Kensington, the City of Westminster, Stoke Newington, and Lewisham; and the highest rates in Holborn, Finsbury, Bethnal Green, Southwark, and Greenwich. The prevalence of

* Including membranous croup. † The death-rates are corrected for variations in sex- and age-constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard. ‡ Deaths from "typhus fever" and "other continued fevers" are not now distinguished in the Registrar General's weekly returns; these two columns are therefore omitted from the Table.

scarlet fever showed a slight increase compared with that in the preceding month; among the various metropolitan boroughs this disease was proportionally most prevalent in Chelsea, Holborn, Finsbury, Southwark, Greenwich, and Woolwich. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals, which had been 1012, 1018, and 1128 at the end of the three preceding months, had further risen to 1206 at the end of last month; the weekly admissions averaged 162, against 124, 127, and 160 in the three preceding months. Diphtheria was rather more prevalent than in other recent months; this disease showed the greatest proportional prevalence in Fulham, Hampstead, Holborn, Finsbury, Shoreditch, Bethnal Green, and Bermondsey. The Metropolitan Asylums Hospitals contained 771 diphtheria patients at the end of last month, against 881, 827, and 801 at the end of the three preceding months; the weekly admissions averaged 102, against 107, 97, and 100 in the three preceding months. The prevalence of enteric fever showed a slight increase over that recorded in any of the three preceding months; the greatest proportional prevalence of this disease was recorded in Paddington, St. Pancras, Poplar, Bermondsey, and Woolwich. The Metropolitan Asylums Hospitals contained 33 enteric fever patients at the end of last month, against 22 and 35 at the end of the two preceding months; the weekly admissions averaged 6, against 5 in each of the two preceding months. Erysipelas was proportionally most prevalent in St. Marylebone, Hackney, Finsbury, Bethnal Green, Stepney, Southwark, and Deptford. The 17 cases of puerperal fever notified during the month included 3 in Greenwich and 2 each in Fulham, Lambeth, Wandsworth, and Camberwell. The 8 cases notified as cerebro-spinal meningitis included 2 in Islington, 2 in Hackney, and 2 in Battersea.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the several boroughs in which the deceased persons had previously resided; the death-rates from all causes are further corrected for variations in the sex- and age-constitution of the populations of the several boroughs. During the four weeks ending July 1st the deaths of 3859 London residents were registered, equal to a corrected annual rate of 11·7 per 1000, against 17·3, 16·7, and 13·2 in the three preceding months. The death-rates last month ranged from 7·9 in Hampstead, 8·5 in Lewisham, 9·1 in Camberwell, 9·5 in Wandsworth, and 9·9 in Stoke Newington, to 13·7 in Finsbury, 13·9 in Stepney and in Southwark, 14·4 in Bermondsey, 14·6 in Shoreditch, and 15·4 in Holborn. The 3859 deaths from all causes included 103 from measles, 13 from scarlet fever, 35 from diphtheria, 62 from whooping-cough, 6 from enteric fever, and 73 (among children under two years of age) from diarrhœa and enteritis. The lowest death-rates from these diseases in the aggregate were recorded in Paddington, Hampstead, Camberwell, Greenwich, Lewisham, and Woolwich; and the highest rates in Shoreditch, Stepney, Poplar, Bermondsey, and Battersea. The 103 deaths from measles were 76 below the corrected average number in the corresponding period of the five preceding years; this disease was proportionally most fatal in Stoke Newington, Shoreditch, Bethnal Green, Stepney, and Poplar. The 13 fatal cases of scarlet fever showed a decline of 19 from the corrected average number, and included 3 in Stepney, 2 in Hackney, and 2 in Battersea. The 35 deaths from diphtheria were slightly in excess of the corrected average number; the greatest proportional mortality from this disease was recorded in the City of Westminster, Shoreditch, Bethnal Green, Poplar, and Battersea. The 62 fatal cases of whooping-cough were 39 fewer than the corrected average; this disease was proportionally most fatal in Kensington, Hammersmith, the City of Westminster, Bermondsey, and Deptford. The 6 deaths from enteric fever showed a decline of 3 from the corrected average number, and included 2 in the City of Westminster. The 73 deaths from diarrhœa and enteritis among children under two years of age included 9 in Islington, 6 in Stepney and in Wandsworth, 5 in Kensington, and 4 each in St. Marylebone, Poplar, and Lambeth. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases (excluding diarrhœa) was 37·4 per cent. below the average.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of Order in Council of April 1st, 1881, Fleet-Surgeon John Kirkup Robinson has been placed on the retired list, at his own request (dated July 18th, 1911).

The following appointments have been notified:—Fleet-Surgeons: E. T. P. Eames, to the *Gibraltar*, and to the *Cambrian*, on recommissioning; J. D. Hughes, to the *Devonshire;* Edward C. Ward, to the *New Zealand*, on commissioning; J. H. Stenhouse, to the *King Edward VII.*, on recommissioning; and E. C. Cridland, to the *Irresistible*, on recommissioning. Staff-Surgeons: H. H. Gill, to the *Cæsar;* K. H. Jones to the *Africa;* and E. S. Tuck, to the *Illustrious*, on recommissioning. Surgeons: M. C. Mason, to the *Gibraltar* and to the *Cambrian*, on recommissioning; F. G. Wilson, to the *Colossus*, on commissioning; G. H. S. Milln and H. B. German, to the *New Zealand*, additional, on transfer of flag; Percy F. Minett, to the *Vivid*, additional, for disposal; C. Ross, to the *Pembroke*, additional, for disposal, and to Royal Naval Hospital, Chatham, vice Wilson, on the *Colossus* commissioning; J. A. Thompson to the *Hercules*, on completing; A. T. Rivers, to the *King Edward VII.*, on recommissioning; A. H. Joy, to the *King Edward VII.*, additional, on transfer of flag, and H. H. Ormsby, to the *Crescent*, and to the *Fiora*, on recommissioning.

Fleet-Surgeon James Henry Beattie has been placed on the Retired List (dated July 24th, 1911).

ROYAL ARMY MEDICAL CORPS.

Colonel R. I. D. Hackett, senior medical officer at Pretoria, has been transferred to India and appointed Principal Medical Officer of the Karachi Brigade. Lieutenant-Colonel H. M. Sloggett, at present serving at Aldershot, has been placed under orders for a tour of service at Malta. Lieutenant-Colonel A. Dodd, in medical charge at Chester, has been selected to succeed Lieutenant-Colonel H. J. Barratt as Senior Medical Officer in the Straits Settlements. Lieutenant-Colonel J. Battersby, who recently retired under the age rule from the Royal Army Medical Corps, has been appointed a Justice of the Peace for the county Tyrone by H.E. the Lord Lieutenant of Ireland. Lieutenant-Colonel R. Kirkpatrick, in medical charge at Devonport, has been detailed for a tour of service abroad during the coming trooping season. Major C. A. Stone, lately commanding the station hospital at Bellary, Madras Presidency, has joined for duty at Cosham. Major F. Smith, D.S.O., sanitary specialist to the Second (Rawal Pindi) Division, has been transferred from Rawal Pindi to Murree. Major P. H. Collingwood, from Crownhill, has taken up duty at Devonport. Major H. M. Nicholls, from Colaba, has been appointed to the Station Hospital at Deolali. Major M. P. C. Holt, D.S.O., specialist in advanced operative surgery to the Sirhind Brigade, has been appointed to the civil medical charge of Kasauli Cantonment. Major J. J. W. Prescott, D.S.O., adjutant of the Royal Army Medical Corps School of Instruction at Newcastle, has been detailed by the War Office for a tour of service with the Southern Army in India. Major G. M. Goldsmith has arrived home on leave of absence from Maymyo, Burma. Major P. J. Probyn, D.S.O., on completion of a tour of service in China, has been appointed to the Irish Command. Major G. B. Riddick has been granted one year's extension of his tour of service in India by H.E the Commander-in-Chief. Captain A. F. Carlyon, from Devonport, has joined for duty at Okehampton. Captain C. E. Fleming, from the Royal Herbert Hospital at Woolwich, has taken up duty at the Military Hospital, Colchester. Captain H. R. Bateman has been transferred from the London District to the Shorncliffe Brigade. Captain W. F. Tyndale, C.M.G., from Dublin, has been placed in medical charge of the effective troops at Kilbride Camp. Captain J. B. Clarke, on return to duty from leave of absence, has been appointed Surgical Specialist at Colchester. Captain G. A. Kempthorne, from Piershill, has been posted to Glencorse. Captain J. H. Campbell, on return from a tour of service in India, has been attached to the Western Command. Captain L. V. Thurston, from Queenstown, has been placed in medical charge of the effective troops at Fethard. Captain G. B. Churchill has been permitted to extend his service in

India for a further period of one year by H E. the Commander-in-Chief. Captain H. W. Long has left the London District for a further period of service on the West Coast of Africa. Captain F. J. Stuart has been appointed a Specialist in the Prevention of Disease and placed in charge of the Bacteriological Research Laboratory at Fyzabad. Captain W. Mitchell, from Ambala cantonment, has taken up duty at the Military Hospital, Subathu, Simla District. The following Lieutenants have been selected by the War Office to proceed to India for duty with the Northern Army during the coming trooping season: S. S. Dykes, W. H. O'Riordan, P. S. Tomlinson, F. W. M. Cunningham, A. S. M. Winder, and V. P. Hutchinson.

INDIAN MEDICAL SERVICE.

Colonel G. W. P. Dennys has taken over the appointment of Inspector-General of Civil Hospitals in the Central Provinces. Lieutenant-Colonel A. Buchanan has taken up duty as Civil Surgeon at Amraoti. Lieutenant-Colonel C. F. Fearnside has been appointed by the Home Department of the Government of India for duty in the Madras Presidency. Lieutenant Colonel P. J. Lumsden, agency surgeon in Beluchistan, has been granted seven months' leave of absence home from India. Major J. M. Woolley has been appointed Senior Medical Officer at Port Blair. Major F. N. Windsor has been confirmed in his appointment as Chemical Examiner, Bengal Presidency, and Professor of Chemistry in the Medical College, Calcutta. Major A. T. Gage, superintendent of the Royal Botanic Gardens at Calcutta and of cinchona cultivation in Bengal Presidency, has been granted two and a half months' privilege leave of absence. Major B. H. Deare, civil surgeon at Darjeeling, has been appointed to officiate as First-class Civil Surgeon during the absence on leave of Lieutenant Colonel D. G Crawford. Captain R B. S. Sewell has been appointed Surgeon Naturalist to the Marine Survey of India. Captain C. F. Marr, medical officer of the 90th Punjabis, has been selected to officiate as Medical Storekeeper to the Government of Bombay, in succession to Major F. E. Swinton, who has been granted eight months' leave of absence home from India. Captain Denham White has joined the staff of the Presidency General Hospital at Calcutta. Captain J. H. Burgess has been appointed Specialist in Advanced Operative Surgery to the Ninth (Secunderabad) Division.

TERRITORIAL FORCE.

Royal Army Medical Corps.

1st Home Counties Field Ambulance, Royal Army Medical Corps: Lieutenant Arthur T. Falwasser to be Captain (dated June 12th, 1911).

1st Lowland Field Ambulance, Royal Army Medical Corps: Neil MacInnes to be Lieutenant (dated June 19th, 1911).

3rd North Midland Field Ambulance, Royal Army Medical Corps: Lieutenant Philip W. Turnor resigns his commission (dated July 22nd, 1911).

3rd South Midland Field Ambulance, Royal Army Medical Corps: Charles Edward Kynaston Herapath to be Lieutenant (dated April 1st, 1911).

1st Northumbrian Field Ambulance, Royal Army Medical Corps: John Hare (late Cadet Lance-Corporal, Durham University Contingent, Senior Division, Officers Training Corps) to be Lieutenant (to be supernumerary) (dated May 27th, 1911).

Yorkshire Mounted Brigade Field Ambulance, Royal Army Medical Corps: Major William K. Clayton to be Lieutenant-Colonel (dated Jan. 1st, 1911).

2nd West Riding Field Ambulance, Royal Army Medical Corps: Major William McG. Young to be Lieutenant-Colonel (dated April 1st, 1911).

THE ST. JOHN AMBULANCE BRIGADE.

The Duke of Connaught, Grand Prior of the Order of the Hospital of St. John of Jerusalem, inspected on July 22nd the members of the Prince of Wales's Corps (London District) of the St. John Ambulance Brigade in Hyde Park. The total number of all ranks on parade was 1136, including 182 nursing sisters. The Duke of Connaught, in expressing his great satisfaction at the smartness of the brigade, said that the St. John Ambulance Association, which had much increased in numbers since it was first formed, was a great asset to the nation, which owed to the officers, men, and nursing sisters a debt of gratitude for the splendid work which they were doing.

Correspondence.

"Audi alteram partem."

THE POSITION OF THE PRESENT REFORM MOVEMENT IN ANÆSTHETICS.

To the Editor of THE LANCET.

SIR,—With your kind permission I should like to be allowed to make a few remarks on the three letters which have recently appeared in your columns upon the above subject.

The first of these letters, from Dr. J. F. W. Silk, appeared in your issue of July 15th. All I can say in reply to such a letter is that I deeply regret to find that there is anyone of Dr. Silk's position who is so unmindful of the high character and responsibilities of the branch of practice in which he is engaged that he is content to allow that branch of practice to remain in its present unsatisfactory position and to associate himself with those ignorant and unqualified persons who at the present moment are permitted, by defects in our legislature, to render their fellow-beings unconscious by means of highly toxic drugs. None are so blind as those who will not see, and if Dr. Silk prefers to keep his shutters up and miss a sunrise which many of us hope in our declining years to look back upon with pleasure he is perhaps more to be pitied than blamed.

The second letter in your last week's issue is from the pen of my old friend, Dr. George Foy, whose contributions to the subject of anæsthesia are so well known. I mention the fact that Dr. Foy is an old friend of mine because if I do not do so someone will discover the existence of this friendship and will address a special letter to you, Sir, concerning it. Those members of the profession, however, who know Dr. Foy will realise that what he says is dictated by a desire to further a cause in which he is interested, and not by any personal considerations. I have no hesitation whatever in endorsing his contention that any seeming lack of enthusiasm in the reform under consideration is due to the fact that the passing of the measure we desire is a mere matter of time.

The third and last letter follows that of Dr. Foy in your issue of July 22nd, and is written by Mr. H. Nelson Hardy in reply to my letter in THE LANCET of July 1st. I am glad to find that Mr. Nelson Hardy admits that if there is to be legislation at all "it should commence by rendering it illegal for unqualified persons to administer such potent drugs except under the immediate supervision of a qualified medical man." The admission puts the seal, so to speak, upon the main question, for, as pointed out in your annotation of July 8th, it has already been decided by all the leading academic and professional bodies concerned that legislation in regard to anæsthetics is highly desirable in the public interest. The only outstanding difference, therefore, between Mr. Nelson Hardy and myself is in regard to methylated chloroform, and I think, perhaps, I may be able to influence Mr. Nelson Hardy in his opinions as to this particular brand by relating the following episode, particularly as those concerned in it were the very individuals upon whose dicta Mr. Nelson Hardy seems to rely. I happened to be one of those who some years ago were invited to witness (1) the administration of absolutely pure chloroform—i.e., chloroform obtained in a crystalline form by freezing methylated chloroform, and (2) the deadly effects of the resulting mother liquor. An animal—I believe a dog—was obtained, and in order that it might be subsequently subjected to the influence of the dangerous mother liquor it was anæsthetised as a preliminary by the pure chloroform. Unfortunately the animal succumbed under the influence of the pure drug, and it therefore became necessary to anæsthetise another animal. This having been done—I believe with ether—some of the highly toxic mother liquor was introduced into its circulation, in order to demonstrate the fatal results that would immediately follow. Unfortunately, however, for those responsible for the demonstration, it was found impossible to kill the animal with the mother liquor. Knowing as we do the uncertainties of demonstrations in anæsthesia, we must not, of course, attach too much importance to the incident. At the same time it is not without its significance. In the light of recent experiments it is practically certain that the first animal died from a high vapour concentration—such a concentration, in fact, as would kill in

spite of the purest drug being employed. I express no opinion as to the failure of the mother liquor to destroy the second animal. I merely quote the circumstances as observed by me on the occasion in question. In conclusion, I would submit to Mr. Nelson Hardy and to all those who hold strong views as to methylated chloroform being responsible for difficulties and accidents, that if they wish to make out a case they must be prepared to explain the fact that a large number of anæsthetists annually conduct thousands of chloroform administrations with methylated chloroform without accidents. At the same time I should welcome any inquiry that would help to settle this particular point and would gladly coöperate in any such investigation.

I am, Sir, yours faithfully,

London, July 24th, 1911. FREDERIC HEWITT.

SALVARSAN ("606") AND MERCURY IN THE TREATMENT OF SYPHILIS.

To the Editor of THE LANCET.

SIR,—In THE LANCET of July 8th, 1911, p. 121, there appeared several replies to an article I wrote on the above subject in your issue of June 24th, p. 1691. The writers, being supporters of salvarsan, naturally tried to ignore the patent fact that the article was primarily written to vindicate the utility of mercury in the treatment of syphilis, as well as to show that the alleged superiority of salvarsan had not by any means as yet been demonstrated either on clinical grounds or on pathological tests if we accept a negative Wassermann as our test. Neisser found the test negative in only 10 per cent. of cases after salvarsan. Other workers have had somewhat similar experiences. I also agreed to differ in THE LANCET of Sept. 25th, 1909, and Jan. 8th, 1910, with Dr. Stopford-Taylor and Dr. R. W. Mackenna in supporting the superiority of inunctions over grey oil injections of mercury in the treatment of early syphilis. They now accuse me of unreasonable antipathy to injections of mercury in order to discount the views on injection of salvarsan. I still use grey oil injections, however, for *military convenience* for out-patients, but Dr. Stopford-Taylor and Dr. Mackenna, who formerly extolled mercurial injections to the sky, have abandoned their first love for salvarsan.[1] The unreasonable antipathy to mercurial injections, therefore, would not appear to rest so much with me as with the writers, who no longer use them. I have not "changed my medical politics with my coat."

From a *clinical* standpoint, my views on inunctions were expressed years before the days of Schaudinn's valuable discovery or the Wassermann-Neisser-Bruck reaction. Mr. H. W. Bayly, another of my critics, speaking of Wassermann tests, quite recently informed us "that 82 per cent. of cases treated by inunction and 35 per cent. of cases treated by injection showed some effect of treatment after only three months. As far as I have gone, therefore, my conclusion is that inunction is the best form of administration of mercury, and I gather that Mr. McDonagh's large continental experience leads him also to this opinion. Calomel injection seems much better than pill treatment, but not so good as inunction, as estimated by the Wassermann reaction. Potassium iodide and the arylarsenates have no effect on the Wassermann reaction, as far as three months' treatment is concerned."

Mr. J. E. R. McDonagh (London Lock Hospital), at the meeting of the British Medical Association in 1910, records valuable testimony when he says that a patient "should, before the disease has become generalised, receive the most active and vigorous form of treatment possible. Mercury, in the form of inunctions, is more potent in this respect than when given in any other form. ..... Working at the Wassermann reaction on the continent I found that it was *almost a rule* to obtain a '*negative*' reaction after a patient had had a course of *inunctions*, or less frequently injections." As Mr. McDonagh has applied the Wassermann test in over 5000 cases his words carry very great weight. In a series of cases at Malta in 1910 70 per cent. gave a positive reaction after a full course of 2–3 years' mercurial injections. Cases on their second, third, and fourth courses of injection were positive in 80 per cent.

I quoted only a few of the reported cases of optic neuritis and optic atrophy following the use of salvarsan. The alleged *suggestio falsi* is non-existent in my article, but apparently has originated in the inner consciousness of Dr. Stopford-Taylor and Dr. Mackenna, who, in their zeal for salvarsan, deny these recorded cases. They are vouched for, however, by persons of unimpeachable good faith and experience. The fact that Dr. Stopford-Taylor met with one or two cases of optic neuritis under mercurial treatment, presumably by injections, does not invalidate the fully recognised fact that numerous deaths and other toxic lesions have occurred under salvarsan. These have increased in numbers since I wrote my article, and there are several more deaths, bringing the number to 34 recorded cases in a year.

I think most people will also concur in the general accuracy of my statement—"that syphilis, unlike cancer, sleeping sickness, and kala-azar, is not a fatal disease." I do not think that because I hold this view I necessarily "live in a fool's paradise," as suggested by Dr. Stopford-Taylor and Dr. Mackenna. The inference should be quite clear that the above three *necessarily* fatal diseases might possibly warrant experiment with a dose of a highly poisonous drug, which, according to Dr. Stopford-Taylor and Dr. Mackenna, is capable of killing three adults, and, as in the case of chloroform, the patient commonly signs a book before taking it owing to the risk. Owing to the fact of there being at present only two cases of syphilis in hospital at Malta, and 160 performing full military duty without any signs of the disease, in a garrison of 6800 men, I am perfectly justified on the facts in vindicating to the uttermost the utility of mercury and potassium iodide in common with a vast number of other persons, if we can judge by recorded testimony in medical literature.

In reply to Mr. Bayly, who questions my views and experience on mercury and inorganic arsenic by the mouth, I reported the personally recorded observations of 18 years' specialised clinical experience without a death which enabled me to take a level-headed view of the proposition. As regards salvarsan, I quoted views and experience of other persons, as independent *primâ facie* testimony is necessarily more convincing to unprejudiced minds. I see that at a discussion on the recent position and treatment of syphilis (*Proceedings of the Royal Society of Medicine*, July, 1910), at which both Mr. Bayly and I spoke, he (Mr. Bayly) states "that he does not find Dr. Fleming's technique so reliable as Wassermann's original technique, as *modified* by me."

Mr. Boas recently lays great stress upon the importance of carrying out all Wassermann's reactions in a quantitative manner—a method which is impossible in the case of all the ordinarily suggested *modifications*. Mr. Boas obtained much better results, and stated that the Wassermann reaction has not, and *will not, obviate the necessity for clinical observation* in syphilis, but it must be undertaken by a person well versed in serological technique if the results are to be taken as being beyond reproach. In further reply to Mr. Bayly, Ehrlich insists that after an injection of "606" the patient should stay in hospital to prevent accidents, &c. In the army we ordinarily deal with very early syphilis, but how could cases ever be discharged from hospital in 24 hours, as inferred by Mr. Bayly, with unhealed chancres or contagious lesions? But admitting only 10 per cent. relapses under salvarsan is another indirect way of claiming 90 per cent. beneficial results. I conclusively showed, and others have shown, that as regards relapses the results under mercurial treatment are as good as or better than salvarsan. The small band of English workers who have dared to criticise salvarsan number three according to Mr. Bayly—namely, Mr. Ernest Lane, Mr. C. F. Marshall, and myself.

In conclusion, I will only refer to the valuable papers of Mr. Pusey and Mr. McKenna of Chicago in the *Journal of the American Medical Association*, January and March, 1911, which are instructive. Mr. Pusey states "that Ehrlich's hopes for '606' were based on animal experiments. Ehrlich recognised, as do others, that experiments on syphilised animals with the agent were not conclusive for man, and he turned over the remedy to clinicians for trial in human syphilis." He quotes Fischer, Lesser, Gaucher of Paris, and Finger of Vienna in support of his view "that salvarsan does not cure syphilis, and that we are not justified in holding out to patients any hope of cure by it, but it may prove a useful remedy, with mercury, however, as before, our chief dependence."

Mr. McKenna of Chicago states: "My own experience with

[1] THE LANCET, May 27th, 1911, p. 1412.

salvarsan and the observations I have made of this work, carried on both in this country and in Europe, lead me to the conviction that under no circumstance should salvarsan be used without also using mercury or the iodide."

John Hunter, in 1786, condemned the "ungrateful and unsettled mind of man" in his endeavour to obtain a substitute for mercury in the treatment of syphilis. He wrote: "If there is such a thing as a *specific* mercury is one for the venereal disease ..... yet mankind are in pursuit of other specifics for the disease, as if specifics were more common than diseases." His clinical observations on induration in the chancre, in my opinion, as a guide to early syphilis, is a vastly superior and more reliable sign than a *modified* Wassermann test, but even under the best auspices the margin of error with Wassermann tests is still very large, which accounts for Mr. Boas's craving for *clinical* confirmation of syphilis. I sympathise with this view, and I suggested long ago the necessity for standardising the test; at present there is a very great discrepancy in the results of various observers, and mistakes are not infrequent.

In reply to Mr. Ernest Scholl *pro* Meister, Lucius, and Brüning, Limited, who states that he writes with Ehrlich's authority, up to August, 1910, there were only 1000 cases *published* which had been treated by salvarsan. According to Mr. Bayly, Erhlich definitely stated (Oct. 5th, 1910): "I have before me the reports on over 9000 cases treated with salvarsan." Mr. Scholl says: "Salvarsan was only placed on the market generally (not only on the English market) on Dec. 15th, 1910, after 60,000 doses had been supplied free, with which about 40,000 cases were treated." Ehrlich says 9000 cases treated, but Mr. Scholl says 40,000 treated, which is a large difference. Where are the *cases* published? From August to October or even December, 1910, is a short period of time, as claimed by me. This patent preparation is registered in England under the trade name of salvarsan. The high price tends to limit criticism by precluding its more general use by medical practitioners. If, as Mr. Scholl says, 60,000 *free* doses were first given away, the fact of a free issue has possibly necessitated the present high cost, which is 7*s*. for a single dose. If humanity at large, as is claimed, is to be benefited, surely this could have been better effected by putting the preparation on the market at a much lower price.

My opinion is that mercury has been conclusively proved to be vastly superior to salvarsan in *average* cases of syphilis whether judged from a clinical standpoint or Wassermann tests. As an auxiliary drug in the treatment of syphilis, salvarsan will no doubt be useful in selected cases, but mercury comes first, and potassium iodide is a close rival.

I am, Sir, yours faithfully,

Malta, July 17th, 1911. H. C. FRENCH, Major R.A.M.C.

To the Editor of THE LANCET.

SIR,—I have read Mr. Bayly's letter in THE LANCET of July 22nd, and hasten to express my thanks to him for having designated me as an "authority of eminence" and also an eminent authority within the space of a few lines; though the vocabulary of his eulogies appears to have its limitations, I take the compliments for exactly what they are worth. In conclusion, I would merely remark that if Mr. Bayly had any genuine desire to ascertain my attitude towards salvarsan he need only have given himself the trouble to pay one visit to the Male Lock Hospital to which, as he has already informed your readers, he is the pathologist. He would then have made the surprising discovery that I had been in the habit of using salvarsan in appropriate cases ever since it was first placed on the market.

I am, Sir, yours faithfully,

Queen Anne-street, W., July 24th, 1911. J. ERNEST LANE.

INFECTIOUS DISEASE IN SCHOOLS.

To the Editor of THE LANCET.

SIR,—The regulations issued by many educational authorities with regard to the periods of exclusion of infected children and of contacts in elementary schools appear to me to be in some respects so exacting as to defeat their own object. With the amount of medical supervision at present available the duty of excluding children on account of illness falls almost entirely on the school teachers. Whilst it is no doubt our duty as school medical officers to see that the periods of exclusion are ample, and to err, if at all, on the side of safety, it is essential that we enlist the support of the head teachers in the work and that they should appreciate the necessity of the procedure. The teachers and the education authority are anxious to keep up the average attendance, and it behoves us as school medical officers to give this aspect of the question every consideration, having due regard to the health of the children.

The rules adopted by many education authorities are in some respects much more strict than the code adopted by the Medical Officers of Schools Association, who might be expected to adopt an adequate margin of safety. Thus in the trivial disease mumps the usual rule in elementary schools is to exclude an affected child for a month, whereas the Schools Association are content with a fortnight. Again, in the case of measles the corresponding periods are four weeks and two weeks respectively. In another trivial disease, German measles, an exclusion of three and four weeks is demanded, whilst the Medical Officers of Schools Association require only 10 days from the appearance of the rash. If mumps and German measles are only infectious for periods of 14 and 10 days respectively, it is obviously unnecessary to keep the children away on their account for a longer period. It is, of course, true that infants with lung complications after measles may require a full month or more before they are in a fit state to resume attendance, but older children are usually fit after a much shorter time.

I am not at all sure that it would not be better in the interests of the school under existing circumstances to do away with exclusion of contacts in the case of the non-fatal diseases—chicken-pox, German measles, and mumps. The procedure is comparatively useless when parents freely send their children to school with the diseases fully developed. So long as the teachers find children in this condition present in the assembled class, it can hardly be expected of them that they will be enthusiastic in excluding contacts in infected families for three weeks, with the consequent disastrous results to their attendance. The periods of exclusion of infected children also should in all cases be reduced to a safe minimum in order to encourage the teachers to watch for and to exclude at once the suspicious cases in the earlier stages of the disease.

I am, Sir, yours faithfully,

Guildford, July 19th, 1911. R. W. C. PIERCE.

VACCINATION IN REGARD TO LIFE ASSURANCE.

To the Editor of THE LANCET.

SIR,—The position of your correspondent, Dr. C. Killick Millard, is a little puzzling to the ordinary reader. On the one hand, he regards vaccination as a serious drawback to the detection of early cases of small-pox, and suggests that we should be better without it. On the other hand, he "regards vaccination as the greatest triumph of preventive inoculation, and would never dream of attempting to fight small-pox as a medical officer of health without its aid." He advocates vaccination of contacts, and is prepared as a *dernier ressort* to recommend the immediate vaccination of the whole community. Are not these two pronouncements somewhat inconsistent with each other? Will not the vaccination of contacts render these persons dangerous in the future? One trembles to think of what may be the result in 15 or 20 years' time of the suggested wholesale vaccination of the community. Perhaps, however, he is not serious in this and does not believe that the necessity will ever arise—at all events in Leicester. The whole tenour of his letter supports this idea. Leicester has been anti-vaccinationist for a quarter of a century and Leicester still lives. It is true there have been a few outbreaks—a few hundred cases and a few deaths—but these are mere trifles not worthy of serious consideration compared with the great cost of general vaccination and revaccination.

Well it must be admitted that Leicester has suffered less from small-pox than some of us think she deserves. One can imagine a burglar who has lived handsomely by his profession for a quarter of a century and yet who, by great wariness, combined with extraordinarily good luck, has never been convicted of anything more serious than stealing a spoon.

One can imagine also the pride he will display among his friends and the contempt he will express for the man who lives by mere work. And yet, after all, his would-be imitators often find that burglary is not the safest and most profitable of professions.

But, seriously, one would like to know what it is that Dr. Millard really wants now that the country generally has decided to follow the lead of Leicester. Does he propose to prohibit vaccination, under a penalty, except where it is recommended by a medical officer of health? Because if not (and possibly even if so) there will still be many children vaccinated who will grow up and possibly take small-pox in a mild form and consequently spread it. Dr. Millard makes much of the case of "the child, Annie L., who caused the outbreak in the Mile-End Infirmary resulting in 30 cases with eight deaths." He seems to hold this child, or those who caused her to be vaccinated, personally responsible for the outbreak! Does it not occur to him that if Annie L. *and the whole community among whom she lived* had been unvaccinated probably 50 others would have taken the disease from the source, whatever it may have been, from which she was infected? Of course, Annie L. would probably have had the disease in a more severe and recognisable form, but equally probably the whole 50 would not.

Small-pox is not *always* a severe disease even among the unvaccinated, although it is so much more frequently than among the vaccinated. The antivaccinationists of Leicester could have told Dr. Millard this. I have known cases of small-pox mistaken for chicken pox in unvaccinated children, even in the presence of an outbreak. The real reason why mild cases of small-pox are often overlooked is because what Dr. Millard regards as the obsolete system of public vaccination has rendered small-pox so rare that the great majority of people, including not a few medical men, have never seen a case. Thanks, however, to the enlightened lead of Leicester and the docile following of the whole country, this lack of experience is likely before many years to be remedied. The country will then have the opportunity of "fairly trying" the Leicester system. I sincerely hope the result may not prove more disastrous than it has been at Leicester.

I am, Sir, yours faithfully,
F. W. STANSFIELD,
Public Vaccinator, Reading.

July 22nd, 1911.

To the Editor of THE LANCET.

SIR,—In your issue of July 22nd Dr. C. K. Millard, medical officer of health, Leicester, refers to Mr. W. H. Jalland's excellent article, part of which appeared in THE LANCET on June 17th, on Vaccination in Regard to Life Assurance. Dr. Millard lays great stress on the "missed" cases of small-pox, and speaks of them as essentially a product of vaccination. His theory appears to be that infantile vaccination could be safely discarded because of these missed cases. He mentions in support of his contention that the case which caused the recent outbreak of small-pox in Mile End directly resulting in 30 cases with eight deaths *was a vaccinated case*. "Will anyone assert," he asks, "that it is probable the same unfortunate mistake would have been made if the child had been unvaccinated?" Leicester provides a distinct answer to this in the affirmative, and the results in Leicester were much more disastrous than at Mile End.

Dr. A. Warner, the resident medical officer of the isolation and small-pox hospitals, and assistant medical officer of health of the borough of Leicester, contributed an article on cases selected from the Leicester epidemics to which Dr. Millard refers, in the *Practitioner*, October, 1904, concluding as follows:—

> Personally, I do not believe that unrecognised cases in those who have previously had small-pox or who have been previously vaccinated play an important part in the spread of the disease to the unvaccinated. For if there be a severe type of the disease prevalent the modification by passage through a single resistant person is not sufficient to make the disease appear very mild in the unvaccinated person. Therefore it is recognised and measures for its control adopted. But when the disease is of a very mild type it may be equally well unrecognised in the unvaccinated, for the mildness is then not so much due to increased resistance as to an attenuated infection. Indeed, the epidemic of 1903 was started simultaneously by two unvaccinated girls having unrecognised attacks, since when many similar cases have occurred.

Dr. Millard advocates drastic changes on the so-called experience of Leicester; he himself admits that the type of the epidemics there has been singularly mild and that the good fortune of Leicester under those circumstances might not have been secured under different conditions. If epidemics followed by hundreds of cases, as in Leicester, can occur, started by "missed" unvaccinated cases, where is the advantage of dropping infantile vaccination because of "missed" cases?

I am, Sir, yours faithfully,
ARTHUR DRURY, M.B., C.M. Edin.

Halifax, July 24th, 1911.

THE NATIONAL INSURANCE BILL.

To the Editor of THE LANCET.

SIR,—I should be glad if I might, through your courtesy, be permitted to state that a copy of the letter which was published from me in your last issue is being sent to all the Members of both Houses of Parliament. The following statement has been added to it by way of introduction, as they could hardly be expected to gauge without further explanation the extent of the infliction with which we are menaced. Even within our own ranks too few seem to realise the danger threatening the higher interests of the profession, or to understand that the great position to which she has earned every claim can only be secured for her by faithfulness to her own high standards.

THE NATIONAL INSURANCE BILL AND THE PROFESSION OF MEDICINE.

The other side of the question, the hearing of which should always precede legislation, has not been referred to in the Bill and has not yet been stated by any of its critics or even of its threatened victims: it has not been placed before our legislators. The Bill and all the discussions thereon have considered exclusively the development of the medical advantage to be obtained for the insurers and for the State, and the "*lowest figure*" at which State medical service could be exacted from the profession short of actual spoliation and sweating. But the advantage and the development which ought to be secured for the other contracting party under any even-handed State contract have not yet been even mentioned. They are in danger of being overlooked in a settlement affecting for an indefinite period the vital interests of the profession, and therefore of the nation. The letter in THE LANCET of July 22nd (p. 250) sets forth that part of the case for the profession which has been passed *sub silentio*. It calls attention to the solid acquired claims of the profession to "treatment with honour" far above those level terms of "equivalent advantage," which are now also being denied it under the clause of "the lowest figure." The only consistent attitude for the profession is "*Dedi ut des.*"

I am, Sir, yours faithfully,
WILLIAM EWART.

Upper Brook-street, W., July 25th, 1911.

A MEMORIAL TO DR. C. W. LONG.

To the Editor of THE LANCET.

SIR,—A letter just received from the eldest daughter of Dr. C. W. Long tells me that the University of Pennsylvania, of which Dr. C. W. Long was a graduate, proposes to place in its medical school a bronze memorial medallion of her father. The unveiling ceremony is to take place on March 30th, 1912. The Provost of the University (Dr. Smith) "believes that for the purpose in mind, that of accentuating our recognition of Dr. Long's achievement, the anniversary of the first use of ether in surgery (March 30th) will be the most suitable date."

The plaster model of the medallion, which is much admired, is the work of a medical graduate of the University, Dr. R. Tait McKenzie, who enjoys more than a local reputation as a sculptor.—I am, Sir, yours faithfully,

July 24th, 1911. GEORGE FOY.

A QUESTION IN EUGENICS.

To the Editor of THE LANCET.

SIR,—I desire to raise an interesting point which has recently presented itself to me, and to obtain an expression of opinion from the profession generally. To state the matter shortly, a man, who has an epileptic son 12 years of age, desired to have the lad sterilised to prevent him from having children if he should live to a marriageable age. The method of sterilisation is not the question—whether by castration, vasectomy, or X rays—but the legal and moral aspect of the case. Has a father the right to have his son sterilised, and is a surgeon legally and morally justified in carrying it out? I am, Sir, yours faithfully,

July 18th, 1911. M.S.

*** We leave these questions to our readers, in accordance with the writer's request.—ED. L.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Royal Visit to Edinburgh.

DURING the stay of Their Majesties at Holyrood, the King and Queen paid a private visit to Edinburgh Royal Infirmary on July 19th. They were received at the entrance by the Lord Provost of Edinburgh, the superintendent, Colonel W. P. Warburton, C.S I., I.M.S. (retired), and the treasurer, Mr. W. S. Caw. As the visit was a private one no guests were invited, but there was a large gathering of the managers and medical staff. The King and Queen visited Ward 7 on the surgical side, where Lord Pentland presented Professor F. M. Caird, the surgeon-in-charge of the ward. The King named this ward "The King George Ward." On the medical side Ward 30 was visited, this ward and Ward 7 (surgical) being the only two unnamed wards in the infirmary. Dr. Byrom Bramwell and Dr. G. A. Gibson, the physicians-in-charge of the ward, were presented to Their Majesties, and the Queen before leaving named the ward "The Queen Mary Ward." Afterwards the King and Queen paid a visit to the kitchen and before leaving the institution they signed their names in the visitors' book. After leaving the infirmary Their Majesties drove along Teviot-place and halted at the steps of the Students' Union, where an address of loyalty was presented by the President of the Union. At Bruntsfield Hospital on the previous day Her Majesty the Queen had declared open the new wing of the hospital. At both institutions Their Majesties most kindly endeavoured to notice individually by a smile or bow or kind word every patient in the wards through which they passed, and at Bruntsfield Hospital Queen Mary, after having passed along the side of one ward and out through the verandah expressed a wish to return to the ward, as she had omitted to notice the patients on the other side. At the door of the hospital there was stationed a guard of honour of the Scottish Women's First Aid Corps The Queen, during her passage through the hospital, shook hands with the lady practitioners and other officials who were stationed in the various wards.

Honours to Edinburgh Medical Men.

Before the conclusion of the Edinburgh visit His Majesty conferred the honour of knighthood on Dr. Thomas Smith Clouston and Dr. James Ormiston Affleck, honours which, as the profession in Edinburgh know, are well deserved. Sir Thomas Clouston, who had a distinguished career as a student, early turned his attention to asylum work, and after holding for ten years the post of medical superintendent of the Cumberland and Westmorland Asylum, Carlisle, was appointed superintendent of the Royal Asylum for the Insane, Edinburgh, from which post he retired in 1908. During his tenure of office at the Royal Asylum he brought about great improvements in the treatment, nursing, and housing of the insane, perhaps the most outstanding achievement being the completion of Craig House about 21 years ago. During his administration the revenue derived from the better class of private patients increased from £8000 to £35,000 per annum. Three weeks ago he received the degree of LL.D. from the University of Edinburgh. The University of Aberdeen had already conferred on him a similar honour in 1907. He has held the offices of President of the Medico-Psychological Association, President of the Edinburgh Medico-Chirurgical Society, and President of the Royal College of Physicians of Edinburgh. Among his writings perhaps the best known are "Clinical Lectures on Mental Diseases" and "The Hygiene of the Mind." For a time he acted as editor of the *Journal of Mental Science*. He formerly held the post of lecturer on mental diseases at the University of Edinburgh. Sir James O. Affleck is well known in Edinburgh as a practitioner and consultant. He graduated as Doctor of Medicine in the University of Edinburgh in 1869. He later became lecturer on practice of medicine at Surgeons' Hall, and was appointed assistant physician to the Royal Infirmary. In 1885 he became full physician and lecturer on clinical medicine in the infirmary. He was thrice appointed examiner in medicine and clinical medicine at the University of Edinburgh, and for many years acted as examiner in medicine for the Royal College of Physicians. In 1908 he received the degree of LL.D. from the University of Edinburgh. He holds the post of consulting physician to the Edinburgh Royal Infirmary, to the City Hospital for Infectious Diseases, and to the Royal Maternity Hospital. He has for some time acted as one of the medical members of the board of management of the Royal Infirmary, and his interest in that institution and in the improvement of the equipment and of the work of the nursing staff has been of great value to the infirmary.

New Victoria Dispensary for Consumption.

As the result of the Coronation appeal for £12,000 to erect a new Victoria Dispensary for Consumption in Edinburgh, the first list of subscriptions, published on July 19th, showed that a sum of £3593 had been already subscribed.

Edinburgh Royal Infirmary: Presentation to Colonel Warburton.

At a meeting of the managers of Edinburgh Royal Infirmary held on July 24th a silver cup was presented to Colonel W. P. Warburton, I.M.S., C.S.I., on the occasion of his retiring from the position of superintendent of the infirmary. The presentation was made by the Lord Provost on behalf of the subscribers, past and present members of the board of management.

Occurrence of Phthisis in Glasgow.

The statistics for last year relating to phthisis in Glasgow are now available. Such statistics, however imperfect at present, are rendered possible by the fact that phthisis became compulsorily notifiable in Glasgow on Jan. 1st, 1910. During the year 3205 primary notifications were received, of which 1308 were from practitioners in private practice and 1897 from medical men in public practice. Other 385 cases were registered on information contained in the hospital admission and dismissal sheets of the Glasgow and Govan Parish Councils, and from the death registers, making in all a total of 3590 cases for the year, which is equal to an attack-rate of 4508 per million. The deaths registered during the same period numbered 1033, representing a death-rate of 1297 per million persons. In connexion with this it is interesting to note the examination of milk samples collected by the veterinary surgeon of the corporation during the year, for investigation with reference to the presence of tubercle bacilli. Of 675 samples of milk examined 466 were from country byres, 163 from town byres, and 46 from byres whence milk is supplied to the city fever hospitals. Of the samples from country byres, 6, or 1·29 per cent., were found to be tuberculous, while from town byres 2, or 1·23 per cent., were affected. Both rates are considerably below those of former years, but the authorities state that it would probably be erroneous to assume that this indicates a sudden and striking reduction in the prevalence of tuberculosis among cattle.

Small-pox Accommodation in Glasgow.

In the course of an exhaustive memorandum bearing on the requirements of Glasgow in regard to hospital accommodation, the medical officer of health for the city states that the most urgent demand is for small-pox accommodation because of the proved unsuitability of the present small-pox hospital site. During the past 40 years a permanent provision of 150 beds proved sufficient to meet all the requirements of the limited outbreaks of small-pox which occurred between the major prevalences of the early "seventies" and 1901. The population of those years, however, was better protected by infantile vaccination than is now the case, owing to the operation of the Vaccination Act of 1907. The proportion of children certified as successfully vaccinated in infancy reached on an average 86 per cent. during the "eighties" decade and 84·5 per cent. during the "nineties." As the result of the passing of the Vaccination (Scotland) Act of 1907, however, the proportion of children successfully vaccinated fell to 75 per cent., the numbers exempted through conscientious objection on the part of the parents being 2183 in 1908 and 2653 in 1909. Making allowances for increase of population during the next 20 years a present provision of 200 beds is required, but on a plan which will admit of rapid extension to 600 beds when occasion arises.

July 25th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The National Insurance Bill.

ON July 19th, at a meeting in Dublin of the members of the combined Irish Medical and British Medical Association Committee, it was decided to appoint a deputation to wait upon the Chancellor of the Exchequer and to assure him that they would prefer to be treated in the National Insurance Bill in the same way as their English and Scotch medical colleagues; but that if it was decided to eliminate medical benefits from the Bill, then, of course, they had nothing more to say. It is stated that in Ireland both the Trades Councils and the Friendly Societies (which are branches of the corresponding English institutions) are totally opposed to leaving out medical benefits, and, indeed, if this is done, it will lead to endless confusion. Suppose a worker under the scheme wants a certificate that he is unable to work, no one but a medical man can give this, and if the worker says he cannot afford to pay for it, who is to come to his assistance? Further, as the Friendly Societies are enquiring, if a tradesman who is under the scheme in England or Scotland comes to reside in Ireland, does he cease to be able to avail himself of medical benefits? One could understand the position of those who recommended that the Bill should not apply to Ireland at all; but to try to make it applicable, and yet, at the same time, to leave out the medical benefits, shows little constructive ability in legislation, or even knowledge of public health; because, though matters are improving, Ireland has still a high death-rate from tuberculosis, and hence has great need for sanatoriums. Yet if medical benefits are excluded, so will sanatoriums be also.

New Labour Ward for the Rotunda Hospital.

The governors of the Rotunda Hospital have issued a special appeal for funds to complete a new labour ward in the hospital without drawing on their ordinary funds. In the last 20 years the number of patients has increased from 1599 to 2596 in the year. It is proposed to equip as two labour wards a large ward formerly used as a nurses' dormitory at a cost of about £1400. The Master suggests that benefactors might make themselves individually responsible for special parts of the work.

Congress of the Royal Sanitary Institute.

The twenty-sixth annual Congress of the Royal Sanitary Institute was opened in Belfast on July 24th, some 700 being in attendance. There was a reception and luncheon, at which the Lord Mayor presided. The Lord Lieutenant of Ireland, the Earl of Aberdeen, spoke at the luncheon, opened the Health Exhibition, and in the evening installed Lord Dunleath as President, who gave a most interesting address on Sanitary Reform. Sir Lauder Brunton, who was to have presided in the Section of Sanitary Science and Preventive Medicine, was unavoidably absent. In his address, which was read by Professor Letts, he pointed out the progress in the prevention of infectious disease due to discovering sources of infection and isolating the infected. Plague, leprosy, and typhus had been all but abolished in this way. He feared that small-pox was not extinct but only dormant, and the increasing disregard of vaccination might result in a serious epidemic. Tuberculosis he expected to become in a few years as rare as leprosy. He referred to the close connexion between mental defect and tuberculosis, the nature of which demanded investigation. The fresh-air cult was sometimes carried to extremes. He endorsed the idea of a pure milk Bill, and urged caution before embarking on the expenditure of a lot of money on sanatoriums. In the section on Hygiene of Childhood Sir John W. Byers, in his presidential address, considered the national importance of bettering child hygiene demonstrated by the large proportion of the total number of deaths that occurred during infancy and the early years of life; by the fact that places having high infant mortalities continued to suffer a high mortality-rate during the first 20 years of life. He said that the amount of sickness in any place varied approximately with the number of deaths, and that a high infant mortality-rate denoted also a high infant deterioration. Hence, efforts to secure the best child hygiene would result not only in a lowered infant death-rate, but in increased physique and higher mental development of children, lessened sickness, and lessened mortality up to adult life. The influences causing wastage of infant life he classified as (1) those due to the habits and homes of the people; and (2) those due to maternal ignorance. It has been found at Belfast, even among bottle-fed babies, that in the most unhealthy districts the amount of infant mortality was far less among mothers who were intelligent, who realised their parental responsibility, and who were stimulated in their efforts by regular visits and instruction at babies' clubs. He asserted the necessity for cultivating the public "sanitary conscience," and urged the health authorities to increased efforts towards proper housing, abolition of overcrowding, provision of open-air spaces, good water-supply, adequate sewerage, pure food and milk, and proper measures against infectious diseases. He advocated also the training of women for the duties of maternity and housewifery, the improving of the education of midwives, and the establishment of babies' clubs and child-welfare exhibitions. Lord Aberdeen also addressed this section.

Guardians and Private Practice.

On many occasions the Local Government Board has incited boards of guardians to attempt to come to some arrangement with their medical officers as to the fees that should be charged in private practice. In nearly every case medical men have declined to discuss their private practices with the guardians. A vacancy recently occurred in the Swinford Union for a dispensary medical officer, and a committee of the guardians was appointed to draw up a scale of fees for the government of private practice. Each candidate was asked to sign an agreement to abide by this scale, and of the two candidates who came forward one consented and was elected. It is now for the Local Government Board to decide whether the guardians acted legally in demanding agreement to the scale.

Payment of Substitute for Dispensary Medical Officer after Accident.

In the case of Mr. H. Moorhead, medical officer of the Moate Dispensary District in the Athlone Union, who met with an accident while riding in a point-to-point race which incapacitated him for duty, the Local Government Board, in accordance with the dispensary rules, has sanctioned the deduction from Mr. Moorhead's salary of the sum paid by the guardians to his substitute. The Local Government Board states that "medical officers who for their own amusement engage in a highly dangerous form of sport, such as steeplechase riding, cannot, if injured, insist upon the guardians providing substitutes for them during their temporary incapacity at the cost of the ratepayers."

July 25th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The General Association of French Medical Men.

SOME notable changes have recently been made in the leading officials of the old-established mutual aid society known under the name of the General Association of French Medical Men. Although associations of this description are increasing in number at the present time, the one in question occupied what might almost be called an official position, for its principal officers and the members of the committee of management were selected exclusively from the higher ranks of the profession, being members of the Academy of Medicine, professors of the Faculty of Medicine, and hospital physicians and surgeons. Its reputation was of the best, but it was nevertheless the object of unfavourable criticism by general practitioners, who complained that although created for the benefit of their less fortunate brethren, it was entirely in the hands of the *élite* of the profession—men who in their high position could not realise the hardships and difficulties incidental to some branches of practice. Many unfortunate individuals who had applied to the society for assistance were met by refusals based on an unduly strict interpretation of the rules, and, moved partly by the new spirit of unionism which prevails throughout the whole industrial population of France, certain medical men have for a long time entertained the idea of attacking the system followed by the committee of the General Association. The committee had, in fact, been to some extent imprudent. Its *Bulletin* is sent to every medical man in France, and

by making an attempt to transform this *Bulletin* into a scientific journal it fell into disfavour with the whole French medical press which would have been a loser by such a proceeding. Finally, in refusing to admit certain new members it seemed to cast aspersions on their professional character, raising against them the objection that they were already members of another medical benevolent society whose statutes allowed the reserve funds to be invested in commercial enterprises, especially in pharmaceutical businesses. The majority of the members of the General Association thought that in this matter the committee assumed the right of pronouncing judgment on disputed professional questions without having any authority to do so. At the last election of officers the new candidates supported by the dissentient party were successful, and those who had managed the affairs of the association for many years had to make room for newcomers, younger men for the most part actively engaged in practice. The position of President, which had for a long time been filled by M. Bucquoy, formerly President of the Academy of Medicine, has been bestowed on a provincial medical man, Dr. Lande of Bordeaux, president of the Union of the Medical Syndicates of France. Dr. Darras, the treasurer, is the only one of the former officers who retains his position. This little revolution has caused quite a sensation in French medical circles.

The Treatment of Fractures.

Several of the recent meetings of the Surgical Society have been devoted to an important discussion on the treatment of fractures, and most of the surgeons who take a special interest in this subject were among the speakers. It must be admitted that much diversity of opinion existed. The methods at present in favour among French surgeons are early mobilisation and massage as recommended by M. Lucas-Championnière, Lambret's *appareil à broches* modified by M. Quénu, Hennequin's constant traction apparatus, and suture of the bones. In the discussion M. Thierry, speaking chiefly with reference to fractures of the tibia attended with displacement, had much to say in favour of Lambret's apparatus, although he considered that the insertion of the pins was always a severe proceeding; he therefore preferred suture of the bones, using for this purpose copper wire rather than silver wire; in his opinion suturing prevented the formation of callus, which was undesirable and a deformity. The majority of the members of the society allowed it to be seen that they were not in favour of suturing or in a general way of operations involving loss of blood. M. Rochard recommended Hennequin's constant traction apparatus, which, although it required some dexterity for its application, did not involve any danger and gave very satisfactory results. M. Routier expressed a similar opinion, adding that Professor Delbet's various forms of ambulant apparatus promoted bony union and encouraged the normal action of the joints. M. Picqué spoke in favour of ambulant methods and against suturing of the bones, as he had known it to produce serious infections. M. Sébilleau also condemned suturing. M. Walther expressed his preference for the older methods—namely, the plaster-of-Paris splint or Hennequin's apparatus, according to circumstances; he was also very well satisfied with Delbet's ambulant apparatus; he reserved suturing for cases in which reduction could not possibly be accomplished by means of any apparatus, and in these he obtained immediate coaptation by catgut sutures, afterwards applying a plaster-of-Paris splint with subsequent careful observation. To recapitulate, the majority of the members of the society were opposed to suturing the bones, all of them except M. Thierry reserving it for exceptional cases.

July 24th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Professor von Noorden's Valedictory Lecture in the Old Medical Clinic.

IN the middle of July Professor von Noorden concluded the summer term by delivering to his students an address in which he bade farewell to the old wards in the Vienna Allgemeines Krankenhaus. In a couple of weeks the clinic, of which he is director, will be transferred to the fine new building which has been erected for this purpose a few hundred yards away from the old hospital, and in which the two gynæcological clinics are already accommodated. Professor von Noorden, in the course of his remarks, outlined the history of the old clinic, which he said had occupied its present place since 1846, but was no longer adequate for the requirements of modern medical practice. When in the period from 1846 to 1872 that renowned physician Professor Skoda was head of the clinic, it sufficed for the scientific needs of the time, and even his successor Professor Duchek raised no objection to delivering lectures to the students at the bedside. After Professor Nothnagel was appointed to the clinic in 1882 a lecture-hall and laboratories were erected; since then nothing of the nature of a modern equipment could be had for this clinic, but nevertheless that famous physician's wards and lecture-room were thronged with students. When in 1905 von Noorden was asked to take over the vacant professorship, he accepted it only on condition that a modern institute should be provided for him within a reasonable time. He had to wait over five years, however, and only now will he receive an up-to-date clinic with all the equipment required for the modern investigation and treatment of disease. Patients eligible for admission are no longer received in the old wards, but are sent directly to the new building, whilst the old patients are being dismissed or will be carried to their new beds. The space hitherto occupied by the clinic will be divided up amongst the other clinics still waiting their turn to move into a new and modern house. When all are in the new hospital, the old one will be converted into streets and gardens.

The Disciplinary Control of Medical Men.

The duties of the Medical Councils of this country include the infliction of several kinds of disciplinary correction on medical men infringing the regulations laid down in the Medical Act (*Aerzte Ordnung*). The severest punishment is the imposition of a fine not exceeding 400 kronen (£16) and the refusal of eligibility for an officer of the Council. These penalties are not severe enough, and, in fact, this kind of punishment has no deterrent effect upon delinquents. A certain proportion of the officers of the Councils therefore recommend that a Council should be empowered to remove the name of an offender from the Medical Register for a period not exceeding one year, thereby debarring him from practice for that length of time, and that this penalty should be inflicted by a court of honour (*Ehrengerichtshof*) for serious offences against medical ethics or against the rules of the Council. The proposal has been discussed by several of our medical unions, and has been nearly everywhere rejected, a court of honour not being credited with the necessary impartiality for imposing such a punishment, which would be likely to ruin its victim. Even the regular courts do not strike off the name of a practitioner from the list except in cases of serious crime, because a medical man restrained from practising his profession is generally unable to earn a living by any other means. For this reason it is held that such extensive powers over a medical man ought not to be handed over to a body of fellow-practitioners, and the general feeling of the profession is absolutely against the proposal in question. The prevalence of racial, religious, and national prejudices in Austria makes it inadvisable to entrust so much authority to a few hands.

Medical Men in Parliament.

The new Parliament, which was elected a few weeks ago, contains only a small proportion of doctors of medicine—nine out of 510, or less than 2 per cent., but the support of some 14 other Members may be counted upon in all matters relating closely to our profession. The new House will have several measures to deal with which will have an important influence upon things medical, the question of national insurance, being, as in England, a fruitful source of divergence of opinion between medical men, the Government, and the Krankencassa. The profession has several times shown its determination not to accept for beneficiaries under the Act any higher wage limit than £100 (2400 kronen) per annum. The medical men in Parliament will have to do their utmost to avert the threatening danger from their professional brethren, and to convince the legislature that the Act will be futile if the majority of medical practitioners are opposed to it.

July 24th.

NOTES FROM CHINA.

(FROM OUR OWN CORRESPONDENT.)

Mr. Dugald Christie, C.M.G.

MEDICAL men in China are pleased at the inclusion of Mr. Christie's name in the Coronation honours list. He is one of the senior medical missionaries of the Far East and has had a fine career at Mukden in Manchuria, where he has remained since his arrival in China close on 30 years ago. In 1884 his first hospital was burnt down accidentally, but was soon replaced by a larger and better building, which in turn was destroyed during the Boxer outbreak. In no way daunted Mr. Christie again rebuilt his hospital, and during the Russo-Japanese war this institution was filled by wounded soldiers of both sides, as well as Chinese, whom Mr. Christie collected from the battlefield. Though rendered unobtrusively, his services were recognised by the Czar and the Emperor of Japan, who both sent him decorations and letters of thanks. Throughout the recent plague epidemic this courageous medical missionary was the right hand of the Viceroy Hsi Liang and his staff, and was rewarded for the heavy work entailed by the implicit trust the Chinese authorities put in him and the way they followed out his advice. At present he is working hard to establish a medical school in the historic capital of Manchuria, and it is expected that the college will be completed next October. Not only the foreign community in North China, but the Chinese as well appreciate very much the official recognition he has received from the King.

Health of Shanghai.

During the past three years I have sent you an annual summary of the health report of Shanghai, as it gives a fair indication of sanitation in Treaty Ports in China, though, notwithstanding the large extent of its foreign settlement, the public health of Shanghai is better managed than in any of the other ports. This city is fortunate in the possession of an able and energetic medical officer of health, Dr. A. Stanley, who, with his staff of four inspectors and 20 assistant inspectors and the help of Dr. A. Moore and Dr. C. Noel Davis, keeps up a systematic examination of the whole settlement, and is able to carry out prophylactic measures in a way which is reflected satisfactorily in the low mortality rate compared with that of other large ports. In a population of 13 536 foreigners and 488,005 Chinese the death-rate from all causes was 20·2 per 1000 foreigners and 17·5 per 1000 Chinese. Last year there were six human cases of plague which were ascribed to the increase of rat infection in a sanitary subdistrict which borders on a pestiferous district under Chinese control, where no precautions are taken. The incidence of small-pox was considerable. 46 cases were notified among the resident foreign community, of which 13 were fatal. Among Chinese there were 304 deaths from small-pox, as compared with 143 and 863 the preceding two years. There were many cases of choleraic diarrhœa, but no case of true cholera was found where the diagnosis was confirmed by the laboratory. Typhoid fever remains an important sanitary factor in Shanghai; there were 23 cases of it, with 16 deaths. In nearly all the cases where the origin was investigated obvious breaches of the rules of health as laid down in the public health notice were observed. There were no deaths registered from Mediterranean fever, and the case mortality from diphtheria is steadily diminishing, probably owing to a more general use of antitoxin, which is now one of the staple products of the laboratory and is issued free to any indigent patient.

Scarlet fever, which is practically unknown in the tropics, now appears to have come to Shanghai to stay since its introduction by foreign immigrants in 1900 As would be expected with a recently introduced disease against which evolution has afforded no natural immunity, scarlet fever has been of a virulent type among the Chinese. It is probable that the passage of the disease through the susceptible Chinese has led to an intensification of the virus, so that it is more fatal to foreigners also. There were 32 cases among foreigners, and a case mortality of 21 8 per cent. The prevalence of tuberculosis remains at the same high level, and the heavy death-rate (669 deaths in all) from this disease is significant of local conditions of overcrowding, against which at present there is no legislation. Indiscriminate spitting and deficient air space are factors which prevail in every town and village throughout the empire and demand a heavy toll, heavier no doubt than the figures indicate, as dislike of disinfection measures results in many deaths being hidden or intentionally returned from other causes. Quite a number of cases of malarial fever, mostly of the benign tertian type, are contracted in and around Shanghai. Beri-beri has diminished, 16 cases as against 78 last year, and this improvement is held to be attributable to the measures of disinfection of body vermin among the prisoners in gaol. Dysentery, with liver abscess as a not infrequent sequel, continued prevalent. It would appear that, unlike the type of dysentery in Japan, which is bacillar in origin, of relatively greater frequency, and unattended by liver abscess, that which occurs in Shanghai is mostly amœbic in origin and prone to liver abscess.

Ten persons were bitten by dogs and underwent the Pasteur treatment. The virus of rabies in Shanghai is of an exceptionally intense character, the period of incubation being shorter than the rabies met with in dogs in Europe. Cattle plague severely affected the dairies during the year. Immunisation by Koch's gall method was offered to all the Chinese dairies but almost invariably refused. The public health laboratory appears to be a busy institution. 20,599 specimens were examined during the year for pathological diagnosis, including 19,559 rats, of which 249 were found plague infected. Over 17,000 glycerinated calf vaccine tubes were sent out during the year.

Peking, June 26th.

Obituary.

HERBERT TIMBRELL BULSTRODE, M.A., M.D. CANTAB., L R C.P. LOND , M.R.C S ENG., D.P H.,

MEDICAL INSPECTOR TO THE LOCAL GOVERNMENT BOARD, AND LECTURER ON PREVENTIVE MEDICINE AT CHARING CROSS HOSPITAL MEDICAL SCHOOL.

WE deeply regret to record the sudden death of Dr. Herbert Timbrell Bulstrode, which occurred on Friday morning last, July 21st, at his house in Palace Gardens-terrace, Kensington. He was the son of the Rev. George Bulstrode, a well-known clergyman, rector of St. Mary Stoke, Ipswich, and Canon of Ely, and was born at Gatcombe, in the Isle of Wight, where his father was rector at the time. He was educated at Emmanuel College, Cambridge, and at the medical school of St. Thomas's Hospital. At Cambridge Bulstrode could only have revealed to his more intimate friends the capacities for great work that lay in him, for he contented himself with filling the ordinary curriculum of a medical student, taking the degree in Arts and later in Medicine with no difficulty, but with no marked distinction. He was, however, already known to his personal friends as being singularly interested, far more than men of his years generally are, in large questions. He read quite outside the ordinary professional line the works of great men, with the deliberate intention to find out the pith of their teaching, and thus acquired, even while a student, a judgment which is unusual in what with all well-educated young people is essentially the cocksure period of existence. At St. Thomas's Hospital he again made no special effort to distinguish himself in examinations If he had applied himself to work for them more directly there is no doubt he would have come out near the top, but success in examinations did not appeal to him, and he passed through his medical course without carrying off any prizes, qualifying at the Colleges in 1886 and 1887, proceeding to his medical degree in the latter year, and obtaining the M.D. in 1890. But he was recognised among his fellow students as a man of more than ordinary ability. He was seen to be one who could not only talk but think, and while he formed strong opinions he was able to give expression to them clearly and to defend them forcibly and fearlessly. His readiness to put forward his views, to defend them, and to attack and cross examine on the views of others sometimes conveyed the false impression that he was self-opinionated. He really preserved a most open mind, and his main object in debate or conversation was to get at the truth and to stimulate his friends to think for themselves and to give reasons for the beliefs which they held and the opinions which they voiced.

Although he gained no class distinctions his merits did not pass unnoticed at St. Thomas's, for he was duly appointed house physician under the late Dr. J. F. Payne, with whom he remained a fast friend in after years.

In 1892 he was appointed to be one of the medical inspectors of the Local Government Board. The enormous increase of sanitary administration that was just developing gave a man like Bulstrode an unequalled opportunity. His industry was reinforced by the judgment which he had been so careful to educate, and from the first it became clear that the department would have in him a thoroughly capable administrator. For the first few years of office he carried on the routine duties of a medical inspector, in the course of which he was engaged in many interesting investigations, the results of which will be found in the Government reports and in many instances in our own columns. But later his name became more particularly associated with two branches of State medicine—namely, the prevention of tuberculosis and the protection of the populace from the evils of a vitiated fish-supply. In 1901 the British Congress on Tuberculosis brought together in this country some remarkable and variable masses of opinion with regard to the prevalence of tuberculosis, its relation to certain social factors, the reasons for its spread and also for its decrease. Sharp diversities of view in respect alike to its origin and spread helped to interest both medical men and public in what is at the present moment one of our greatest public health problems. Sir William Henry Power, at that time medical officer of the Local Government Board, had begun to publish in his reports, under the heading of auxiliary scientific investigations, inquiries which could hardly be attempted by any observer in the absence of facilities given by a Government department; and Bulstrode was told off to inquire on behalf of the Board into the various aspects of the tuberculosis question. The first fruit of his arduous and valuable work was the Milroy lectures delivered before the Royal College of Physicians of London in 1903 on the Causes, Prevalence, and Control of Pulmonary Tuberculosis. These lectures, which were printed in full in THE LANCET, showed how exhaustive Bulstrode's investigations had been during the intervening time, how painstaking his consultation of authorities, and how thorough his visits to various localities before feeling himself at liberty to make any definite pronouncement from the preventive point of view. For reasons which are clearly set out in the lectures he came to the conclusion that pulmonary tuberculosis is an infectious malady, possessing a communicability of a low order, and he set out his arguments in exactly the way to counteract the mischief which had been done by the public belief that consumption is catching like small-pox or whooping-cough. With regard to the virtues of notification of tuberculosis Bulstrode was not in the first instance very much convinced of the great good to be obtained in this manner; indeed, his original idea was that it would be well to limit notification to those cases of tuberculosis which, owing to their domestic conditions, were sources of danger to people about them, a suggestion which amounted to saying that the general sanitary surroundings of such persons should be notified to the medical officer of health rather than the disease. As his experiences of the value of notification grew Bulstrode modified this view, but he was the least bureaucratic of officials, and always maintained that notification of tuberculosis, unless conducted with great care, or if possible on some largely voluntary principle, might trespass upon the freedom of the subject. Education of children in the principles of health, compulsory insurance against sickness, the provision of sanatoriums, and lastly, the better housing and improvement of the conditions of employment of the working classes, were the factors upon which Bulstrode was prepared to rely in 1903 for an organised struggle by the State against the ravages of tuberculosis, and of the fortunate end of such a struggle he had no doubt.

Bulstrode was next commissioned to make special inquiry into the sanatorium treatment of tuberculosis, and during the following five years, in the intervals of his regular employment as an inspector, he visited most of the important sanatoriums for the treatment of tuberculosis at home and abroad, the result being the volume entitled "Sanatoria for Consumption," a standard work which was published by the Local Government Board. In this work will be found a mass of important facts derived from personal investigation of the various aspects of tuberculosis, from discussions with medical officers of health wherever special lines of attacking the various problems of prevention had been developed, and from detailed information obtained on the spot as to the prevalence of tuberculosis in foreign countries and the ways of dealing with it. Bulstrode satisfied himself, from the evidence which he had thus collected and collated, that sanatorium treatment in a sufficiently early stage gives a chance of curative results; while the isolation of potentially infectious persons from the community, and the education that such persons under a sanatorium *régime* receive in the method to be taken against the spread of infection must, he asserted, prove of pre-eminent value to the community. His study of the behaviour of tuberculosis in the German Empire, especially in relation to the improvement of the social position of the working class, is one of the most instructive portions of the volume, and has been found of particular significance just now by all men, medical or lay, who have grappled with the proposals of the National Insurance Bill.

The second important subject with which Bulstrode's name will be associated in preventive medicine is the spread of disease by shell-fish. He had written as early as 1895 on the possible spread of disease by the eating of shell-fish living in impure waters, a subject to which great attention had been called by Dr. Arthur Newsholme, the present medical officer of the Local Government Board, at that time medical officer of health of Brighton. Bulstrode was appointed by the Board to make an investigation of the serious outbreaks of typhoid fever in 1902 at Portsmouth, Southampton, and Winchester, in the latter two cases the outbreaks following public banquets. The outbreaks showed that in spite of the issue of several Local Government Board reports but little change had been made in those sewerage systems, to the effects of which the specific pollution of oyster-beds could clearly be traced, while the sanitary authority in the existing state of the law appeared to be helpless, there being no legal power vested in the authority by which the sale of oysters from contaminated sources could be prevented. Bulstrode made important reports on these outbreaks, and following upon them the hands of the local authorities were strengthened and throughout the country the risks from the sale of contaminated shell-fish were much abated. He continued to carry on and supervise such work at the Local Government Board, and as recently as last April made to the Board a comprehensive and highly instructive report on the relation of enteric fever and gastro-enteritis to the consumption of shell-fish. From this report it became easy to see that under existing conditions it is possible for large sums to be expended upon sewage purification works and yet for the effluent to contain enormous numbers of sewage bacteria, while the difficulty of periodic outflows of untreated, though highly diluted, sewage through the storm overflows remains. Bulstrode in this report took his readers upon an instructive journey around the English and Welsh littoral, and showed by means of maps and descriptions in the text the actual conditions which obtain in every place of importance, with respect to the position of the shell-fish and to the methods adopted for storing and cleansing them prior to consumption. The revelations made were decidedly disquieting, and there is no shadow of doubt left as to the necessity for legislative action.

Bulstrode's excellent scientific and administrative work was fully recognised by his colleagues and the medical world at large. He was the British delegate to the International Congress on Tuberculosis in 1905 at Paris; he on more than one occasion represented the Royal College of Surgeons of England at conferences of hygiene; he was a member of the Departmental Committee on Food Preservatives; and contributed articles on these subjects to the great medical systems and journals. He was also chairman of the Board of Studies of Hygiene of the University of London, lecturer on preventive medicine at Charing Cross Hospital, president of the Epidemiological Section of the Royal Society of Medicine, and examiner in hygiene for more than one well-known medical faculty.

We deeply regret that this valuable and busy life should have been terminated so suddenly and by an untimely death, for Dr. Bulstrode was only 52 years of age. He did work that will bear fruit for long periods to come, and both

THE BRITISH MEDICAL ASSOCIATION.

SEVENTY-NINTH ANNUAL MEETING IN BIRMINGHAM.

THIS year's Annual Meeting of the British Medical Association, which is still in progress as we go to press, is the fifth that has been held in the capital of the Midlands. Previous meetings at Birmingham took place in 1834, in 1856, in 1872, and in 1890. The arrangements for the present gathering have been admirably organised, and the whole affair has already proved itself to be a great success. Birmingham is particularly well suited for a meeting of this sort, because the main buildings of the city, which lend themselves appropriately to the scientific and social functions of the Association, are concentrated for the most part within a small area.

Although surrounded by densely populated manufacturing areas Birmingham is a clean city, thanks to its elevated situation. Even within the precincts of the city there is abundant evidence of its great association with the manufacture of iron and steel, but the offensive emanations of the great foundries, alkali and acid works in the adjoining "Black Country," do not appear to reach Birmingham.

One of the first impressions forced upon the visitor who is addicted to the frequent use of soap and water is the luxury of a soft water-supply. Birmingham long ago realised the necessity of going far outside its own resources of rivers with an uncertain flow, and of wells with a doubtful endurance, and closed promptly with the proposal to secure an unlimited supply of soft water from the Welsh hills. The scheme was realised in 1908, and there is now available from the watershed of the Elan and Claerwen a supply of water amounting to 72,000,000 gallons daily. Luckily it is not a moorland acid water, but is faintly alkaline and without action upon lead.

With equally commendable perspicacity the sanitary authorities grasped early the meaning of the developments of biological experiments in regard to the disposal of sewage. The whole of the sewage of Birmingham, representing a population of over 500,000, is now treated by means of bacteria beds, and one of the most interesting demonstrations offered to the visitors was the complete resolution of a nuisance and source of evil into simple innocuous materials by a biological process the success of which is due to careful engineering in able hands.

The Exhibition of Surgical Instruments, Drugs, and Foods was held in the Bingley Hall, a place of meeting which has associations with great political movements and prize agricultural stock. The Bingley Hall, in fact, is the Agricultural Hall of Birmingham. It covers a large area, but only about one-third of its space was allocated to the "annual museum." There was an obvious falling off in the number of exhibitors on this occasion, the list being a comparatively small one. It was not easy, moreover, to find a stall presenting exhibits of a really novel kind, or an array of materials which were not already familiar to the regular attendant at this annual event, though novelties were to be seen, as we indicate elsewhere. There was little to be seen that was of real scientific interest, apart, that is to say, from an obvious commercial motive. It was most gratifying, however, to note how lively is the interest taken nowadays by manufacturers of fine products in the scientific side of their work. The standardisation of drugs, both physiological and chemical, furnishes an illustration of this excellent attitude. The exhibitors were well supported by the organising authorities, who did their best to make the attendance a satisfactory one. The exhibition was opened on Tuesday, July 25th, by the President-elect, who was accompanied by the President and the Lord Mayor of Birmingham. We commence this week in another column a review of the more important exhibits shown, following the same classification of them which we have adopted on previous occasions.

The representative meeting began on Friday of last week, July 21st, in the large theatre of the Midland Institute, next door to the town-hall, which had been converted into a general reception room for all those attending the annual meeting. Immediately behind the institute and the town-hall is the large University building in Edmund-street, and this has been devoted to the work of the 16 scientific sections.

The sittings of the representatives ended on Tuesday morning, July 25th, and were followed that afternoon by the annual general meeting, which always marks the commencement of what may be called the annual meeting proper. The religious services were followed by successful garden parties by Lady Lodge and by Mrs. Saundby, wife of the President-elect of the Associaton; and on the same evening, in the Grand Hall of the University of Birmingham, at Bournbrook (some four miles from the heart of the city), Sir Henry Butlin, the retiring President, vacated the chair for Professor Saundby, whose Presidential address is printed in another part of this issue of THE LANCET. The first day's programme ended with a pleasant smoking concert in the Drill Hall, organised by the Birmingham and District General Medical Practitioners' Union, and presided over by Dr. H. W. Langley Browne.

At the annual general meeting on Tuesday afternoon Sir Henry Butlin resigned his office as President, and in a few felicitous words introduced his successor and placed the presidential badge of office around Professor Saundby's neck. Both the retiring President and the President-elect were received with great enthusiasm and were welcomed by graceful speeches from Professor J. T. J. Morrison and Dr. Bruce Gough. The vote of thanks to Sir Henry Butlin for his distinguished services to the Association and to the medical profession was carried with loud and prolonged acclamation, every member present rising from his seat and cheering warmly. The tributes paid to the retiring President were applauded in a very striking manner, which showed the esteem and affection in which he is held by all members of the Association.

On Tuesday afternoon a service was held for the members of the Association at the Pro-Cathedral when the Bishop of Birmingham, Dr. Gore, preached the sermon. There was a good attendance and, as on previous occasions, the collection was divided between the British Medical Benevolent Fund and Epsom College. Dr. Gore made an excellent appeal on behalf of these institutions. A service was also held at the Church of the Oratory of St. Philip Neri, Edgbaston, the sermon being preached by Monsignor Henry Parkinson, Rector of Oscott College.

Before Professor Saundby delivered his Presidential Address on Tuesday evening, at the University at Bournbrook, the foreign guests of the Association were formally introduced to him, and he offered a welcome to the delegates from the Oversea Dominions. A certificate of honorary membership was then presented to the Right Honourable Joseph Chamberlain in recognition of his great services to tropical medicine,

and this was received and acknowledged on his father's behalf by Mr. Neville Chamberlain. After this the Middlemore prize of the Association was presented to Dr. C. W. Gordon Bryan, for his essay on "Serum and Vaccine Therapy in connexion with Diseases of the Eye." The Presidential Address was attended by a large gathering of members and ladies, and academical dress (as at the religious services and the Lord Mayor's reception) was worn by a considerable number of those present. The new President was supported by the Lord Mayor and the Vice-Chancellor of the University. Over 720 members had registered their names by Tuesday afternoon as attending the annual meeting, and a large proportion were accompanied on their visit by ladies.

A concise and instructive pathological museum has been organised under the superintendence of Professor R. F. C. Leith, in the Pathological and Brewing Laboratories of the University College in Edmund-street, in close proximity to the meeting-rooms of the various scientific sections. Praise is due to Mr. A. W. Nuthall, the honorary secretary of the museum, and to the various honorary secretaries and curators of the ten constituent sections of the museum. The exhibition is excellent. Special subjects are selected for illustration in the divisions of medicine, surgery, gynæcology, ophthalmology, and radiology; and there are many beautiful casts and wax models illustrating diseases of the skin. More than 80 microscopes have been lent by the University to the Museum Committee for this occasion.

The more strictly scientific work of the meeting began on Wednesday, July 26th, when the various sections sat from 10 to 1 o'clock in the classrooms of the University building. The Address in Medicine was delivered at 12.30 on Wednesday in the Midland Institute, and the Address in Surgery on Thursday at the same place and time. Both are printed in this issue of THE LANCET. The handy situation of the institute enabled many of those members who had been engaged in the morning's work of the sections to listen to these two instructive addresses. The most important social and academical events on Wednesday and Thursday were the Lord Mayor's reception, the Degree Congregation, the annual dinner, and a garden party given by Mrs. Gilbert Barling.

It was announced during the course of the meeting that the next annual meeting of the Association would be held in 1912 in Liverpool, and that the President on that occasion would be Sir James Barr, consulting physician to the Liverpool Royal Infirmary.

THE BRITISH MEDICAL ASSOCIATION AND THE NATIONAL INSURANCE BILL.

The Representative Meeting of the British Medical Association, which began its sittings in committee on Friday, July 21st, came on Tuesday last to a definite declaration of policy with regard to the National Insurance Bill, and as a result resolutions were passed as instructions to the Council of the Association, by which body they will be transmitted to the Chancellor of the Exchequer. The demands which reached their definite shape under six headings at the meeting of representatives held in London at the end of May are all maintained. The six headings of these demands are:—

1. An income limit of £2 a week for those entitled to medical benefit. 2. Free choice of doctor by the patient subject only to the consent of the doctor to attend him. 3. Medical and maternity benefits to be administered by Local Health Committees and not by Friendly Societies. 4. The method of remuneration of medical practitioners adopted by each Local Health Committee to be according to the preference of the majority of the medical profession of the district of that committee. 5. Medical remuneration to be what the profession considers adequate, having due regard to the duties to be performed and other conditions of service. 6. Adequate medical representation among the Insurance Commissioners, in the Central Advisory Committee, and in the Local Health Committees; and statutory recognition of a local Medical Committee representative of the profession in the district of each Health Committee.[1]

[1] THE LANCET, June 10th, 1911, p. 1616; July 15th, 1911, p. 194.

The proceedings of the committee were *in camerâ*, and only the resolutions finally arrived at by it were placed before the representative body, which confirmed them all. The demand, however, for a maximum income limit of £2 per week in respect of medical benefits to apply throughout the country was confirmed, with the proviso that in any district in which the local profession considers that the circumstances justify fixing a lower limit than this it should have the support of the Association in so doing. The meeting approved the new suggestion—based to some extent upon a hint given by Mr. Ramsay Macdonald in his speech on the second reading debate—that persons might receive their medical benefit in the form of a contribution to the cost of their medical attendance under private arrangements made by them with medical men of their own selection, instead of in the form of medical attendance arranged by the Local Insurance Authority. Persons whose income is above the statutory or locally agreed limit would take their benefit in the form of a contribution to the cost of their attendance. Persons below the limit would have the option, subject to the approval of the Local Authority, which should consult with the Local Medical Committee, to be appointed in accordance with an amendment placed by the Chancellor of the Exchequer on an Order Paper of the House of Commons on July 25th. The Council was instructed to take every means in its power to carry out the policy of the Association above described, and to ensure a continuance of the efforts already made, with a view to obtaining a statutory fixation of the £2 per week income limit in respect of medical benefits.

THE ANNUAL EXHIBITION.

AN inaugural ceremony has not hitherto been the rule in connexion with the annual exhibition of surgical appliances, drugs, special foods, and so forth, but this year the authorities decided to give the exhibition a fair start with a formal opening by the Lord Mayor of Birmingham, who was supported by the ex-President and President of the Association. The Lord Mayor was given a very hearty vote of thanks by the audience, which comprised a good many of the interested exhibitors. This departure was successful; it introduced at once a large attendance of medical men to the scene, which soon became a busy one. The display of surgical instruments and hospital appliances attracted perhaps the most interest, and on the whole this section of the exhibition enjoyed a larger representation than any other. In magnitude the exhibition could not, of course, compare with the exhibition in London last year, which was officially stated to be the largest collection of exhibits ever brought together under the auspices of the Association. Though, however, the exhibits were not so numerous as before, there was decided evidence of their interesting character, and the exhibitors found plenty to do in pointing out to the visitors the special features of the foodstuffs, drugs, or surgical and hospital appliances which were presented to view. It is true there were many familiar objects shown, but there were also quite a large number of exhibits which attracted interest because they were new.

As on previous occasions, we present again a rapid review of the more important exhibits in the following order: (1) Surgical Instruments and Appliances; (2) Drugs; (3) Foods and Food Products; (4) Sanitary Appliances; (5) Mineral Waters, Beverages; (6) Publications; and (7) Exhibits of a Miscellaneous Character.

I.—SURGICAL INSTRUMENTS AND APPLIANCES.

It is difficult to do justice to this section owing to the large number of instruments and appliances which were shown. All the well-known makers were represented and the stalls of each displayed a profusion of new appliances of the greatest interest to those engaged in advanced medical and surgical practice. There were up-to-date appliances for treatment by radiant heat, light, and electricity, illustrations of the application of radium in disease, and besides there was shown a great number of improvements in the various instruments employed in surgical operations. Invalid beds and hospital furniture were also a feature of this section of the exhibition. It was noticeable that a good many firms who hitherto have confined their attention to the preparation of pure drugs or organo-therapeutic remedies have added to their specialities certain medical and surgical appliances. Messrs. Siemens Bros. and Co., Limited,

of Caxton House, Westminster, were well to the fore with their electric apparatus, and their "oscillothermex," a combined apparatus for diathermic, high frequency, and X ray treatment with oscillating discharges, was inspected with considerable interest. The exhibit included also an admirably designed universal electro-medical apparatus for the application of galvanisation, faradisation, cataphoresis, cautery, and so on. Amongst the exhibits also were some instruments made of tantalum, which in dental use prevents the discolouration of the fillings. The same metal is used in evaporating dishes, forceps, and injection needles. Lastly should be mentioned their demonstration of radium salts, applicators, and other radioactive appurtenances. Close by, the well-known surgical instrument makers, Messrs. Down Bros., of 21 and 23, St. Thomas's-street, London, S.E., showed a very interesting collection of modern surgical instruments conforming to the design of experienced surgeons, while the exhibit included examples of aseptic hospital furniture, operation tables, and so on, which were generally admired. Local skill was represented in the surgical dressings' exhibit of Messrs. Southall Brothers and Barclay of Lower Priory, Dalton-street, and Dale End, Birmingham, who gave illustrations of the different stages of manufacture, from raw material to finished cloth, of gauzes and lints and antiseptic and aseptic dressings. The exhibit of Radium, Limited, of 4, Albert-square, Manchester, served to turn attention to this new development of treatment. This firm provides an apparatus for rendering water radio-active and they also prepare artificial radio-active earths of guaranteed efficiency for local applications. There was shown also a recently designed apparatus for the inhalation of radium emanations combined with oxygen and fountain distributers for the distribution of radium emanations in the air for simple inhalation treatment. Messrs. Chas. Hearson and Co., Limited, of 235, Regent-street, London, W., exhibited their new anhydric electric incubators, and an electric high-speed centrifuge was shown working at a speed of 9000 revolutions per minute. A well-known local firm, Messrs. Philip Harris and Co., Limited, of Edmund-street, Birmingham, gave special prominence to the hospital aseptic furniture of their manufacture. It included a portable operating-table made under the suggestion of Mr. Bernard J. Ward, which can be made adjustable with great ease for the Trendelenburg, lithotomy, and horizontal positions. There was demonstrated at this stall also a special snow apparatus producing solid carbon dioxide in cones for producing anæsthesia for minor operations. Besides special foods and an interesting series of pharmaceutical products, Messrs. James Woolley, Sons, and Co., Limited, of Manchester, exhibited their all-glass aseptic sprays and syringes, and an adjustable truss which offers decided advantages. An interesting exhibit was that of Messrs Spencer, Heath, and George, Limited, of 48 and 52, Goswell-road, London, E C., which comprised some well-thought-out medical and anthropometric apparatus. Amongst the objects shown were plinths, massage tables, booms, rib-stools, and an ingenious "stationary cycle exerciser" for orthopædic gymnastics, providing a frame for lady's or gentleman's use. Messrs. J. Nesbit-Evans and Co., of Floodgate-street, Birmingham, deserve a word of praise for their hospital bedsteads and accessories, including an anti-accident children's cot, an anti-sagging lunatic patient bedstead, a spring wire side epileptic bedstead, a bedside table, and aseptic bed-screen. The Skeffington patent recumbent invalid lifters (address of manufacturers, 49, Ulundi-road, Blackheath, S.E.) received considerable attention, and naturally enough, having regard to the extreme comfort which they offer to the patient in bed and to the convenience which they afford to the medical attendant. The "Skeffington" prevents a weak patient from slipping towards the foot of the bed, maintaining the patient in the sitting posture without any exertion on his part; a patient may be lifted in the sheet bodily so that the bed can be re-made underneath while the patient is still recumbent, and the bedpan can be applied in an easy and undisturbed way. With similar admirable objects in view the apparatus have been made known respectively as the "Anastasia," the "Catharios" (for lifting the patient's sacrum only), and the "Skeffington cushion," a pneumatic cushion which when deflated can be easily withdrawn from the patient's back, and when inflated by a pump gently lifts the sacrum only.

The surgeon found much to interest him in the large assortment of up-to-date surgical instruments presented by the Holborn Surgical Instrument Company, Limited, of Holborn-circus, London, E.C. The Holborn £25 set of instruments adapted for the surgeon commencing to practise makes a very suitable article for presentation. Specimens of hot-air chambers and suction glasses for Bier's treatment were shown by this firm. Mr. G. H Zeal, of 82, Turnmill-street, London, E.C., exhibited many variants of his "Repello" thermometer, an ingenious and accurate instrument which does not require shaking to reset. There were many appliances worth studying at the stall of Messrs. Reiner and Keeler, Limited, of 9, Vere-street, Cavendish-square, London, W. There were, for example, the Edridge-Green colour perception lantern and the same author's classification test and pocket test, and besides an amblyoscope and exophthalmometer.

Messrs. Pocock Brothers, of 235, Southwark Bridge-road, London, S.E., exhibited sections illustrating the material used in padded rooms, besides an indiarubber bed and hospital sheeting with enduring qualities. The stand of Messrs. Mayer and Meltzer (71, Great Portland-street, London, W.) received close attention from surgeons, the instruments shown bearing in so many cases, and quite rightly, the description of "latest." The firm drew attention in particular to an improved aseptic guillotine designed by Mr. Hugh Jones, but we saw many instruments displayed that have been described fully in our columns by their makers. The "Wassmuth's Sanum" Company, of 5, Sloane-street, London, S.W., exhibited a new antiseptic which is described as superior to all other antiseptics on account of its "greater efficacy and harmlessness." Chemically, it is "liquor natrii chloro-borosi." What was correctly described as "an exhibit of the newest ideas in surgical instruments and medical appliances" formed the attraction of Messrs. John Weiss and Son's stall (287, Oxford-street, London, W.). Here was shown "606" apparatus both for intravenous and intramuscular injection. The exhibit included some modern forms of spinal analgesia syringes, saline infusion apparatus, carbon-dioxide snow apparatus, and an ophthalmological section comprising the Edridge-Green lamp for colour test, examination lamps for retinoscopy, and other instruments of value in advanced ophthalmological practice. Messrs. Fassett and Johnson, of 86, Clerkenwell-road, London, E.C., exhibited the well-known and approved standard gauzes, aseptic ligatures, medicinal and surgical plasters of Messrs Seabury and Johnson. Among the exhibits of Messrs. Walton and Curtis, of 190, Broadhurst-gardens, West Hampstead, London, N.W., was the "Curtis" abdominal support, designed by Mr. Arbuthnot Lane, which is found to give direct antero-posterior support without pressure on the hips and to retain its position without the use of perineal straps regardless of posture. The exhibit included a hydrostatic cupper and aspirator invented by Dr. H. Macnaughton-Jones. Surgical dressings were well represented at the stall of the Liverpool Lint Company of Mark Street Mills, Netherfield-road North, Liverpool, two features of the exhibit being their "Vulnoplast" material, which affords a complete dressing with self-adhesive edges, composed of several layers of gauze treated with approved antiseptics. The dressing does away with bandaging or pinning. "Impermiettes" should be mentioned also among the exhibits of this firm. They present advantages over ordinary rubber-coated sheetings owing to their durability. They can be sterilised and cleansed without injuring the fabric. The personal demonstration by Mr. C. A. Hoefftcke (of 21, Woodstock-street, Oxford-street, London, W.) of his extension appliances drew the attention of a good many visitors, and excellent evidence of the value of these appliances in the treatment of tuberculous joints was furnished in a series of skiagrams. The exhibit included an appliance for obtaining extension of the spine in the treatment of scoliosis and caries or injuries to the spine, appliances for fractures, a corset for lateral curvature, and artificial legs made on the same principle as Hoefftcke's appliances for joint disease. The exhibit of Messrs. Reynolds and Branson of Leeds contained many new departures in medical and surgical apparatus. There were apparatus for the injection of salvarsan, for the local application of solid carbon dioxide, for the administration of oxygen alone or with alcohol, for saline infusion, and so forth. There was a profusion also of instruments for minor surgical operations, all well made

and in many cases owing their inspiration to well-known surgeons. Messrs. T. Holland and Son, of 46, South Audley-street, London, W., showed specimens of their well-known instep supports for flat-foot and metatarsalgia, as well as their natural shape boots. The study which this firm has given to the question of a comfortable boot deserves recognition. There were some useful surgical appliances to be seen at the stall of Messrs. Anderson and Dodds, of 11, Broad-street Corner, Birmingham, including a watch-spring pessary introduced by Dr. N. Spriggs, and a device which obviates the inconvenience attaching to the wearing of elastic thigh stockings, by keeping the stocking in its place and preventing it from slipping down the thigh. Much ingenuity marked the appliances shown by Mr. Harry Brook, of 25, Brackenbed-lane, Halifax, which are designed to palliate disfigurements of the face. There were shown here artificial noses, ears, chins, fingers, all designed with the object of concealing loss of feature through disease or accident, and as far as illusion is possible in such cases, these inventions would create it.

Messrs. Claudius Ash, Sons, and Co., Limited, of 5 to 12, Broad-street, Golden-square, London, W., made anæsthetics and anæsthetic apparatus the special feature of their exhibit, which included nitrous oxide gas outfits, and outfits with nitrous oxide gas and oxygen and the appurtenances incidental to the administration of general and local anæsthetics. Messrs. Hawksley and Son of 357, Oxford-street, W., showed a collection of blood-pressure apparatus designed by well-recognised authorities. The exhibit included, amongst other novel appliances, the new portable mercurial hæmometer of Dr. George Oliver, which, apart from being compact, possesses a vacuum chamber which renders temperature effects upon the readings nugatory, and a clinical recording apparatus.

There can be little doubt that this section of the Annual Exhibition grows increasingly interesting each succeeding year, and the present occasion shows that surgical and hospital appliances claim a very big share of the exhibits introduced to the notice of the visitors.

(To be continued.)

Medical News.

UNIVERSITY OF LONDON.—At examinations held in July the following candidates were successful:—

M.D. EXAMINATION.

Medicine.—Phirozshaw Cooverji Bharucha, B.S., University College Hospital; John Webster Bride, B.S., Victoria University of Manchester; Manchersha Dhanjibhai Dorabji Gilder, B.S., University College Hospital; Alexander Edward Gow, B.S., St. Bartholomew's Hospital; Frederick William Higgs, B.S., St. George's Hospital; Ernest Williams Jones, University of Birmingham; David Judah, B.S., and Clement Lovell, B.S., University College Hospital; and Geoffrey Viner, B.S., and Arthur Lowndes Yates, B.S., St. Bartholomew's Hospital.

Midwifery and Diseases of Women.—Elsie Mary Chubb, B.S., London (Royal Free Hospital) School of Medicine for Women; Joseph Bernard Dawson, B.S., University of Birmingham and St. Bartholomew's Hospital; William Poole Henley Munden, B.S., Guy's Hospital; John Hobart Nixon, B.S., St. Mary's Hospital; Alfred Howard Parkinson, B.S., B.Sc., University of Leeds; and Robert Evans Thomas, B.S., University of Bristol.

State Medicine.—Alfred Ball, B.S., and Walter Francis Corfield, B.S., University College Hospital; Matilda Hunt, B.S., London (Royal Free Hospital) School of Medicine for Women and Royal Institute of Public Health; James Jenkins Paterson, B.S., B.Sc., University of Liverpool; Alfred Charles Foster Turner, B.S., St. Thomas's Hospital; Thomas Williams Wade, B.S., University College, Cardiff, and Charing Cross Hospital; and Cuthbert Ferguson Walker, B.S., St. Mary's Hospital and Victoria University of Manchester.

Tropical Medicine.—Daniel Elie Anderson, B.A., B.Sc., London School of Tropical Medicine; Francis Victor Owen Beit, St. Bartholomew's Hospital and London School of Tropical Medicine; Friedrich Grönе, St. Bartholomew's Hospital; John Hanna Murray, University College Hospital and London School of Tropical Medicine; and Charles Cecil Connock Shaw, B.S., St. Mary's Hospital, London School of Tropical Medicine, and Post-Graduate College West London Hospital.

M.S. EXAMINATION.

Surgery.—Cecil Augustus Joll, B.Sc., University of Bristol and University College Hospital; and Edward Leslie Martyn Lobb, Guy's Hospital.

N.B.—This list, published for the convenience of candidates, is issued subject to its approval by the Senate.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—C. B. Hawthorne (Sections I. and II.), Cambridge and Birmingham; J. S. H. Lewis (Section I.), University College Hospital; F. G. Norbury (Section I.), Glasgow; E. H. Roberts (Sections I. and II.), University College Hospital; and W. H. Watson (Sections I. and II.) and R. M. Wingent (Section I.), Guy's Hospital.

Medicine.—N. S. Adler (Section II.), Berlin; A. de Luyck (Section II.), Brussels; A. E. L. Devonald (Sections I. and II.), St. George's Hospital; P. McGinnis (Section I.), Dublin; and E. H. Roberts (Sections I. and II.), University College Hospital.

Forensic Medicine.—E. H. Roberts, University College Hospital.

Midwifery.—A. E. L. Devonald, St. George's Hospital; J. S. H. Lewis, University College Hospital; C. C. Messiter, St. Bartholomew's Hospital; P. J. Montgomery, Middlesex Hospital; C. E. Reckitt, Guy's Hospital; and E. H. Roberts, University College Hospital.

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—N. S. Adler, C. B. Hawthorne, A. de Luyck, and E. H. Roberts.

LONDON SCHOOL OF TROPICAL MEDICINE.—The following students at the school were successful at the examination closing the thirty-sixth session (May–July, 1911):—

*Captain D. Heron, I.M.S., M.B., Ch.B. Edin.; F. Grone, M.B., D.P.H.; E. C. Braithwaite, M.B., B.S. (Colonial Service); L. W. Davies, M.D. (Colonial Service); J. T. Wigham, M.D., D.P.H.; R. E. Drake-Brockman, M.R.C.S., L.R.C.P. (Colonial Service); Major A. Moorhead, I.M.S., M.B., C.M.; N. S. Messiha, Cairo School of Medicine; D. Duff, M.B., B.Ch. (Colonial Service); G. O. Teichmann, M.B., B.S., M.R.C.S., L.R.C.P.; C. A. Crichlow, M.B., Ch.B.; A. T. Ozzard, M.R.C.S., L.S.A. (Colonial Service); W. I. M. Clark, M.B., Ch.B. (Colonial Service); M. W. Fraser, M.B., Ch.B. (Colonial Service); H. R. M. Ferguson, M.B., B.Ch. (Colonial Service); J. Y. Wood, M.B., Ch.B. (Colonial Service); H. S. Gettings, L.R.C.S., L.R.C.P., D.P.H.; S. P. Proctor, M.B., Ch.B.; R. O. Sibley, M.B., L.R.C.S., L.R.C.P.; G. C. Winchester, M.B., C.M.; R. Bury, L.R.C.P., F.R.C.S. (Colonial Service); B. J. Courtney, M.D. (Colonial Service); W. H. Bomford, L.R.C.P. & S.I. (Colonial Service); and J. Bruce Bays, M.D., M.B., M.R.C.S.

* With distinction.

The following students also obtained the M.D. Lond. in Tropical Medicine (Branch VI.):—

D. E. Anderson, M.D. Paris, M.B. Lond.; F. V. O. Beit, Captain I.M.S., M.B. Lond.; F. Grone, M.B. Lond., D.P.H.; J. H. Murray, Captain I.M.S., M.B. Lond., M.R.C.S., L.R.C.P.; and C. C. C. Shaw, Captain I.M.S., M.B., B.S. Lond.

UNIVERSITY OF DURHAM.—At examinations held recently the following candidates were successful:—

DEGREE OF BACHELOR OF MEDICINE.—THIRD EXAMINATION.

Arthur Butterfield, Garfield Carse, Cyril Duncan, Walter Armstrong Elliott, Sarah Louisa Green, Nora Murphy, William Somerville Murray, Charles O'Hagan, and Carina Augusta Barry O'Neill, College of Medicine, Newcastle-upon-Tyne; Lionel Glover Pearson, University of Leeds; and Evelyn Ritson (First-class Honours), Charles Henry Robson, Cedric Overton Shackleton, Arthur Sutcliffe, and Gordon Stewart Woodman, College of Medicine, Newcastle-upon-Tyne.

SECOND EXAMINATION.

Cyril Armstrong, William John Bowden, and Geoffrey Bede Egerton, College of Medicine, Newcastle-upon-Tyne; Henry Hawes Elliot, College of Medicine, Newcastle-upon-Tyne, and Guy's Hospital; Charles Norman Gover, Philip Gunn, Frank Wilson Harlow, and Cyril Jacobs, College of Medicine, Newcastle-upon-Tyne; David Rees Jones, College of Medicine, Newcastle-upon-Tyne, and Guy's Hospital; Robert Rutherford Lishman, Francis Metcalfe, Ernest Charles Gilchrist Parker, and Jane Penman (Second-Class Honours), College of Medicine, Newcastle-upon-Tyne; Hugh Ley Puxon Peregrine, College of Medicine, Newcastle-upon-Tyne, and Guy's Hospital; Home Alexander Playfair Robertson, College of Medicine, Newcastle-upon-Tyne; Eric Knowles Ryan, College of Medicine, Newcastle-upon-Tyne, and University of Sheffield; Philip Savage, Guy's Hospital; Kirton Ivor Seager Smith, College of Medicine, Newcastle-upon-Tyne; Charles Rees Smith, Guy's Hospital; and James Calvert Spence, College of Medicine, Newcastle-upon-Tyne.

FIRST EXAMINATION.

Elementary Anatomy and Biology, Chemistry, and Physics.—Henry Evers (First-Class Honours), College of Medicine, Newcastle-upon-Tyne.

Chemistry and Physics.—John Alexander Charles, Ethne Haigh, George Irving, Hubert Ransome Markham, John Eric Measham, William McDonald Pettigrew, Bertram Sergeant, Alfred Smirthwaite, and Reginald Leslie Wright, College of Medicine, Newcastle-upon-Tyne.

Elementary Anatomy and Biology.—George Gordon Baty, College of Medicine, Newcastle-upon-Tyne; John Francis Carter Braine and Cyril Charles Herbert Cuff, Guy's Hospital; Lionel Basil Frere, College of Medicine, Newcastle-upon-Tyne; Leonard Wilfred Hearn, Sheffield University; Cecil Neild Joseph and Frederick Lisle Newstead, College of Medicine, Newcastle-upon-Tyne; and Douglas Oliver Richards, Guy's Hospital.

Elementary Anatomy.—Harold Kingston Graham Hodgson, St. Thomas's Hospital.

DIPLOMA IN DENTAL SURGERY (L.D.S.).—FIRST EXAMINATION.

Chemistry and Physics.—John Thomas Smith (First-Class Honours) College of Medicine, Newcastle-upon-Tyne; and George Galloway Robertson (Second-Class Honours), College of Medicine, Newcastle-upon-Tyne.

At the Convocation held on July 22nd the following degrees and diploma were conferred:—

Doctor of Medicine.—Edwin Gilbert Emerson Arnold, Richard Henry Bellwood, Henry Glendinning Davison, Horsley Drummond, Patrick Albert Galpin, Charles Westland Greene, Robert William Nevin, and John Ralph Prior.

Doctor of Medicine for Practitioners of 15 Years' Standing.—James Moore Bennett, Richard Dagger, Patrick Joseph Flanagan, Edward Palmer Stewart Gane, William James Hoyten, Henry Percival Johnson, Arthur Edwin Joscelyne, Frederick Charles Langford, William Henry Payne, and Frederick George Meynell Philps.

Doctor of Hygiene (D.Hy.).—Robert Samuel Trotter.

Master of Surgery (M.S.).—Charlotte Purnell.

Bachelor of Medicine (M.B.).—Oscar Frederick Don Airth and John Hamilton Barclay, College of Medicine, Newcastle-upon-Tyne; Richard Murray Barrow, St. Bartholomew's Hospital; Michael Brennan, Joseph Jopling Brown, Eric Lawrence Hancock, Thomas Albert Hindmarsh, and William Hudson, College of Medicine, Newcastle-upon-Tyne; William Hughes, Edinburgh School of Medicine; Frank Hutchinson Kennedy, John Lumb, and Benjamin Bell Noble, College of Medicine, Newcastle-upon-Tyne; John Howard Owen, Guy's Hospital; Elliot Jessie Ramsbotham, London School of Medicine for Women; Felix Stephens Rood, University College, London; Madeline Rosa Shearburn, London School of Medicine for Women; and Eleanor Walkinshaw and Arthur Hyde Wear, College of Medicine, Newcastle-upon-Tyne.

Bachelor of Surgery (B.S.).—John Hamilton Barclay, College of Medicine, Newcastle-upon-Tyne; Richard Murray Barrow, St. Bartholomew's Hospital; Michael Brennan, Joseph Jopling Brown, Eric Lawrence Hancock, Thomas Albert Hindmarsh, William Hudson, Frank Hutchinson Kennedy, John Lumb, and Benjamin Bell Noble, College of Medicine, Newcastle-upon-Tyne; John Howard Owen, Guy's Hospital; Elliot Jessie Ramsbotham, London School of Medicine for Women; Felix Stephens Rood, University College, London; Joseph Albert Sacco, College of Medicine, Newcastle-upon-Tyne; Madeline Rosa Shearburn, London School of Medicine for Women; and Alfred Tulloch Thompson, Eleanor Walkinshaw, and Arthur Hyde Wear, College of Medicine, Newcastle-upon-Tyne.

Degree of Bachelor of Hygiene (B.Hy.).—Helen Grace Clark.

Diploma in Public Health (D.P.H.).—Helen Grace Clark.

UNIVERSITY OF BRISTOL.

At examinations held recently the following candidates were successful:—

FINAL EXAMINATION FOR THE DEGREES OF M.B., CH.B.

Pass-list.—Ernest Edgar Davies, Claude Alfred Heath Gee, Edmund Fairfield Thomas, and Arthur John Ormsby Wigmore.

Passed in Part I.—Maurice Charles Barber, Edwin Vincent Foss, Adolph Gottlob Hieber, Basil John Francis Jackson Taylor, and Colston Wintle.

Passed in Part II. (completing the examination).—Stuart Hardy Kingston.

SECOND EXAMINATION FOR THE DEGREES OF M.B., CH.B.

Richard Irving Dacre, Claude Jocelyn Delubere May, and Arthur Geoffrey Morris.

FINAL EXAMINATION FOR THE DEGREE OF B.D.S.

William John Lennox.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, ROYAL COLLEGE OF SURGEONS OF EDINBURGH, AND ROYAL FACULTY OF PHYSICIANS AND SURGEONS.

At the recent examinations held in Glasgow the following were successful:

First Professional Examination.—Devendra Bharadwaja, India; Thomas Pennington Bremner, Liverpool; Thomas Weir Drummond, Greenock; George Melven Harley, Glasgow; David Andrew Imrie, Glasgow; Charles Clouston Irvine, Arran; Mary Gray Jones, Motherwell; William M'Alpine, Wishaw; James M'Farlane, Paisley; Charles Reade, Glasgow; John Mellon Smeaton, Glasgow; William Templeton, Glasgow; and Thomas Robert Wilson, Garelochhead.

Second Professional Examination.—Andrew Crawford, Glasgow; Verdon Charles Hubert Dearden, Sheffield; John Ramsay Fleming, Airdrie; John Gilchrist, Hamilton; Madeline MacWilliam, Stranraer; Fred. Miller Murray, Glasgow; Alamu Ojo Olaribigbe, Sierra Leone; and Valentine Hutchinson Wardle, Bishop Auckland.

Third Professional Examination.—George Logan Clark, Glasgow; Hariharnath Hukku, Agra; James Grant Morrin, Glasgow; William Nevill Pennant Williams, Wales; James Noonan, Ireland; Evan Edward Owens, Wales; Alexander Morton Robertson, Glasgow; and John Watt, Glasgow.

Final Examination.—Diwan Jai Chand, India; Husain Buksh, Punjab; Harry Joseph Burke, Ireland; Robert Miller Danks, Coatbridge; Colin Hunter, Glasgow; John Boyd Michie, Alva; Francis Patrick Quirk, New South Wales; Morris William Rees, North Wales; William Wood Shorten, Ireland; Abraham Hertz Silverman, Russia; Gulab Singh, Punjab; William Minnis Thomson, Ireland; and James MacMurchy Watson, Glasgow.

FOREIGN UNIVERSITY INTELLIGENCE.

Copenhagen: Dr. Valdemar Henriques has been appointed to the chair of Physiology, in succession to Dr. Ch. Bohr, deceased.—*Kiel:* Dr. Hentze, who has charge of the Dental Clinic, has been granted the title of Professor.—*Jena:* Dr. Roessle of Munich has been appointed Professor of Pathological Anatomy in succession to Dr. Dürck.—*Königsberg:* Dr. Ernst Sachs has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Lausanne:* Professor Askenazi of Geneva has been offered the chair vacated by the death of Professor Stilling.—*Leyden:* Dr. J. P. H. van Kerchoff has been appointed Lecturer on Dermatology.—*Marburg:* Dr. Otto Veit has been recognised as *privat-docent* of Anatomy.—*Philadelphia (University of Pennsylvania):* Dr. John B. Deaver has been appointed to the chair of Clinical Surgery in succession to Dr. E. Martin.—*Naples:* Dr. Michele Pellegrino has been recognised as *privat-docent* of Medical Pathology.—*Sassari:* Dr. Tommaso Casoni has been recognised as *privat-docent* of Internal Pathology.—*St. Petersburg (Military Medical Academy):* Dr. G. W. Fleischer has been recognised as *privat-docent* of Infectious Diseases and Bacteriology.—*Vienna:* An Institute of Experimental Psychology is to be established under the direction of Professor August Stöhr.—*Würzburg:* Dr. Gerhardt, professor in Basle, has been appointed to the chair of Clinical Medicine in succession to Dr. von Leube, who is retiring.

AN AMENDE.

Our attention has been called by Dr. F. G. Clemow, British delegate on the Constantinople Board of Health, to the fact that in an article published in THE LANCET of April 29th, written by Dr. G. Douglas Gray and entitled "A Report on the Plague Outbreak in Manchuria and North China," a passage on p. 1155 is a quotation from an article communicated to THE LANCET two years ago by Dr. Clemow entitled "Some Hitherto Unknown Centres of Plague in the Kirghiz Steppes." We are sure that Dr. Gray would like to make this acknowledgment to Dr. Clemow, while our readers can see that when the quotation occurred the author believed himself to be reciting a passage in an editorial article. We regret that specific reference to the work of the British delegate should have been omitted.

CORONATION MEDALS FOR AMBULANCE WORK.

The King has conferred silver Coronation medals upon the following officers of the St. John Ambulance Brigade in recognition of their valuable services on ambulance duty during the time of the Coronation festivities:—The Chief Commissioner (Colonel Sir James Clark, Bart., C.B.), the Medical Officer-in-Chief (Mr. Edmund Owen), the Lady Superintendent-in-Chief of Nursing Corps and Divisions (Lady Perrott); the following Deputy Commissioners of Districts—Colonel C. J. Trimble, C.M.G., Mr. S. C. Wardell, Colonel G. S. Elliston, C.B., Mr. J. S. Griffiths, Colonel E. Cureton, Lieutenant-Colonel Lees Hall, Lieutenant C. B. Palmer; and the Assistant Commissioner of the Metropolitan or Prince of Wales's Corps (Mr. W. H. Morgan).

LITERARY INTELLIGENCE.

The Oxford University Press announces the immediate publication of a historical treatise on "The King's Evil," by Dr. Raymond Crawford. The volume contains a number of curious illustrations.—The managing committee of the Sleeping Sickness Bureau, Royal Society, Burlington House, London, W., has decided to publish a Quarterly Bulletin dealing with the *Leishmania* group of diseases. Dr. C. M. Wenyon, Protozoologist to the London School of Tropical Medicine, will undertake this part of the work. A list of references is now in preparation and will form the first number. Application for copies of the work should be made to the director, who asks that other publications bearing on the subject may be sent to the Bureau library.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

The following is the prize list of the summer session, 1911:—Barker Anatomical Prize, £31 10*s.*, Miss Eleanor Taylor; Special Prize, £15 15*s.*, T. Mulcahy. Carmichael Scholarship, £15, E Connell. Mayne Scholarship, £8, J. T. Duncan. Medals in Operative Surgery, J. T. Duncan, gold medal; H. J. Burke, silver medal. Stoney Memorial Gold Medal in Anatomy, M. Shipsey. Practical Histology: G. M. C. Powell, first prize (£2) and medal; W. P. Cooney, second prize (£1) and certificate. Practical Chemistry: V. A. Power, first prize (£2) and medal; M. Moran, second prize (£1) and certificate. Public Health and Forensic Medicine: G. N. N. Smyth, first prize (£2) and medal; G. E. Pepper, second prize (£1) and certificate. Materia Medica: G. N. Smyth, first prize (£2) and medal; E. Connell, second prize (£1) and certificate. Biology: N. E. Stephens, first prize (£2) and medal; K. Elms and L. M. Rowlett (equal), second prize (£1) and certificate.—The Barker anatomical prize for 1912 (of £21 for a Dissection of the Phrenic Nerve) is offered for competition and is open to any student whose name is on the anatomical class-list of any school in the United Kingdom.

The preparations entered must be placed in charge of the curator of the Museum, Royal College of Surgeons in Ireland, Dublin, on or before April 30th, 1912. The dissection for which a prize is awarded will become the property of the College. Those competitors who enter dissections for which prizes are not awarded, but which show sufficient merit, may be refunded such amount of the cost of production as the examiners deem fit. Full particulars can be obtained from the curator of the museum.

THE WANDSWORTH MORTUARY.—The condition of the Wandsworth mortuary was against referred to in the course of an inquest last week. The body in question was so badly decomposed that the father of the deceased had been advised not to see it. This state of affairs has on several occasions been the subject of protests by medical men. At the last meeting of the Wandsworth borough council a communication was received from an association of ratepayers asking what steps were being taken with regard to mortuary provision. To the proposal that the association should be informed that the matter was under consideration, a councillor moved that it should be added that the matter had been under consideration for 19 years. The council's consciousness of municipal dignity prevented this from being carried. It is understood that the council is waiting for the re-apportionment of the coroners' districts within the borough of Wandsworth.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—A quarterly court of the directors of this society was held on July 12th. Dr. W. Rigden, Vice-President, took the chair, in the absence of the President. Three gentlemen were elected members of the society and the death of a member was reported. The sum of £1371 was voted for the payment of the half-yearly grants to the annuitants of the charity—namely, 48 widows and 16 orphans. Relief is only granted to the widows and orphans of deceased members, and since the last court five letters had been received from widows of medical men asking for relief, but this had to be refused, as their husbands had not been members of the society. The invested funds of the society now amount to £101,600. Membership is open to any registered medical practitioner who at the time of his election is resident within a 20 mile radius of Charing Cross. The annual subscription is 2 guineas, special rates for life membership varying with the age of the applicant. The next election of members will be on Oct. 11th, and application forms must be sent to the secretary on or before Sept 20th; these may be obtained, together with further particulars, on application to the secretary at the offices of the society, 11, Chandos-street, Cavendish-square, London, W.

ASSOCIATION OF INFANT CONSULTATIONS AND SCHOOLS FOR MOTHERS.—A general meeting of the Society of Infant Consultations was held recently at the Marylebone Dispensary, when Dr. Eric Pritchard explained that the object of the meeting was to consider the proposed scheme of amalgamation with the Department of Schools for Mothers of the National League for Physical Education and Improvement. The new organisation would be called the Association of Infant Consultations and Schools for Mothers, and would have a much wider field of usefulness than under the present conditions. The secretarial duties would in future be carried on by the permanent staff of the League. The new scheme, which was proposed by Dr. F. Langmead and seconded by Miss FitzGerald, was unanimously adopted by the meeting. The aims and objects of the new association are to bring into closer relationship all who are engaged or interested in the work of infant consultations, schools for mothers, and similar institutions; to promote the establishment of such institutions and to advise as to their organisation; to organise conferences and other meetings; to record the experience gained by individuals engaged in the work, and collect literature, statistics, and reports bearing on the subject; to supply such institutions with literature, charts, diagrams, &c.; and to promote coöperation with all societies working for infant welfare. The medical subcommittee will continue the work of the present Society of Infant Consultations and the educational subcommittee that of the Department of Schools for Mothers. The secretaries of the medical subcommittee will have the right, *ex officio*, to attend the meetings of the educational subcommittee, and *vice-versâ*.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

National Insurance Bill Amendments.

MORE than a dozen pages of amendments to Clause 14 of the National Insurance Bill are now down on the notice paper of the House of Commons. The Chancellor of the Exchequer has slightly altered the terms of his amendment, of which notice was given more than a week ago. It now reads: "The regulations made by the Insurance Commissioners shall provide for the arrangements made being subject to the approval of the Insurance Commissioners and being such as to secure that insured persons shall, save as hereinafter provided, receive adequate medical attendance and treatment from the medical practitioners with whom arrangements are so made," &c. The words "save as hereinafter provided" are new.

Sir PHILIP MAGNUS, Dr. HILLIER, Mr. CAVE, Mr. LESLIE SCOTT, and Sir HENRY CRAIK have given notice of their intention to move the insertion of the following provisions in this clause, which deals with the administration of medical benefit: "Every insured person whose income from all sources exceeds one hundred and four pounds a year and who has become entitled to medical benefit shall be entitled, in lieu of medical attendance and treatment (including medicines), to receive an equivalent pecuniary allowance towards the expenses of medical attendance and treatment (including medicines) to be calculated and paid to or for him in accordance with regulations made by the Insurance Commissioners, and any insured person whose income from all sources does not exceed one hundred and four pounds a year, and who has become entitled to medical benefit, shall be entitled to elect in lieu of medical attendance and treatment (including medicines) to receive such equivalent pecuniary allowance as above mentioned. For the purposes of this section the income of an insured person shall be deemed to exceed one hundred and four pounds a year if his income during the calendar year preceding the date when he becomes entitled to medical benefit exceeded that sum, and any question as to the amount of such income shall be determined by the Local Health Committee."

Dr. ADDISON will move the insertion of the following provision: "Subject to regulations by the Insurance Commissioners, an approved society or Local Health Committee by which medical benefit is administered may allow any persons, and may, on the ground of means, require any persons, in lieu of receiving medical treatment and attendance, including medicines and appliances under such arrangements as aforesaid, to make their own arrangements for receiving such medical treatment and attendance, including medicines and appliances, and shall in respect of all persons who have so made their own arrangements contribute towards the cost of their medical treatment and attendance, including medicine and appliances, sums not exceeding in the aggregate the cost which the society or committee would otherwise have incurred in providing medical benefit for them."

Mr. LLOYD GEORGE this week has placed amendments on the notice paper which, if adopted, would make Subsection 3 of Clause 14 read as follows:—

"*A Local Health Committee shall, on the request of any approved society, take over* the administration of medical benefit among such members of the society entitled thereto as may be resident in the county or county borough for which the committee is established, *on such terms as failing agreement may be determined by the Insurance Commissioners;* and *where any such committee has so taken* over such administration there shall in each year be paid out of moneys credited to the society such sum in respect of every member of the society entitled to the benefit and resident in the county or county borough as may *have been so agreed or determined.*"

The alterations which the Chancellor of the Exchequer proposes to make are printed in italics.

An amendment is also tabled by the Chancellor of the Exchequer to make it apparent that the powers of councils of a county or county borough with respect to excess expenditure are optional.

Mr. LLOYD GEORGE has given notice to move the insertion of the following subsection in Clause 47 (erection of sanatoria, &c.):—

"A Local Health Committee may, with the consent of the Insurance Commissioners, enter into agreements with any person or authority that, in consideration of such person or authority providing treatment in a sanatorium or other institution as aforesaid for insured persons recommended by the committee for sanatorium treatment as may be agreed, the committee will contribute out of the funds available for sanatorium benefit towards the maintenance of the institution such annual or other payment, and subject to such conditions and for such period as may be agreed, and any such agreement shall be binding on the committee and their successors, and any sums payable by the committee thereunder may be paid by the Insurance Commissioners, and deducted from the sums payable to the committee for the purposes of sanatorium benefit."

The right honourable gentleman has placed on the notice paper the following new clause in respect to Local Medical Committees:—

"Where a local medical committee has been formed for any county or county borough, and the Insurance Commissioners are satisfied that such committee is representative of the duly qualified medical practitioners resident in the county or county borough, they shall recognise such committee, and where a Local Medical Committee has been so recognised it shall, subject to regulations made by the Insurance Commissioners, be consulted by the Local Health Committee on all general questions affecting the administration of medical benefit, including the arrangements made with medical practitioners giving attendance and treatment to insured persons, and shall perform such other duties, and shall exercise such powers as may be determined by the Insurance Commissioners."

Medical Officers of Health Superannuation Bill.

Dr. HILLIER has introduced into the House of Commons a Bill "to provide for superannuation allowances to medical officers of health employed by local authorities and for contributions towards such allowances by those officers, and to make other relative provisions." It was read a first time. The Bill has the support of Mr. HENRY FORSTER, Sir CLEMENT HILL, Colonel HICKMAN, Mr. JOHN ROBERTSON, and Mr. BARNES.

Pure Flour Bill.

Sir JOHN LONSDALE has introduced a Pure Flour Bill in the House of Commons, and it has been read a first time. Its object is "to prohibit the artificial bleaching of flour, whether by chemical processes of manufacture or by the addition of chemical or other substances."

Experiments on Living Animals.

The Home Office return showing the number of experiments on living animals during the year 1910 under licences granted under the Act 39 & 40 Vict., c. 77, distinguishing the nature of the experiments, has been published. The report is signed by Professor G. D. THANE, and sets forth that nine new places were registered for the performance of experiments, and three places were removed from the register during the year. The total number of licensees was 542. The number of experiments conducted under anæsthetics was 4939. Inoculations, hypodermic injections, and a few other proceedings without anæsthetics numbered 90,792. The total number of experiments was thus 95,731. The returns show that 49,662 experiments were performed by 27 licensees working at eight institutions in the course of cancer investigations. Sir W. THORNLEY STOKER makes the report in regard to Ireland, where 254 experiments were conducted during the year.

Effect of National Insurance on Hospitals.

A deputation representing the British Hospitals Association, the Hospital Saturday Fund for London, and the Central Hospitals' Council of London was received by Mr. LLOYD GEORGE on Tuesday, July 25th, in order that the members of it might put before him their views on the effect of the National Insurance Bill on hospitals. The general view expressed by the spokesmen of the deputation was a fear that the contributions of workmen and employers should be diverted from hospitals, and the work of these institutions restricted and crippled. The Chancellor of the Exchequer declined to regard the anticipations of the deputationists as likely to be realised. Their apprehensions, he thought, would not be justified by results. After the momentary agitation had passed people would do their duty towards hospitals in the same way as in the past. He pointed out that approved societies under the National Insurance Bill were empowered to contribute to hospitals. The right honourable gentleman emphasised the voluntary character of these institutions and suggested that State assistance might bring with it a certain amount of State control. In conclusion he threw out the suggestion that the hospital authorities should confer with the medical profession on the subject, and then they should come to him with some sort of arrangement with respect to those cases which came to hospitals and were taken off the hands of medical men.

HOUSE OF COMMONS.

WEDNESDAY, JULY 19TH.

National Insurance and Maternity Benefits.

Mr. WORTHINGTON-EVANS asked the Chancellor of the Exchequer whether a member of a Friendly Society granting a 30*s.* maternity benefit would, if he continued to subscribe for such benefit, be also entitled to receive the 30*s.* maternity benefit under the National Insurance Bill; and whether the limitation that sickness benefits should not exceed the total wages would interfere with the additional 30*s.* maternity benefit if the sickness benefits already assured equalled the wages.—Mr. ILLINGWORTH (on behalf of Mr LLOYD GEORGE) replied: The right of an insured person to receive maternity benefit under the National Health Insurance will be unaffected by his having effected an insurance for an additional maternity benefit outside the national scheme. The limitation of sickness benefits to total wages does not apply to maternity benefit.

Medical Referees and the Workmen's Compensation Act.

Mr. GILL asked the Secretary of State for the Home Department whether he had further considered the question of appointing a few medical referees who would devote the whole of their time to their duties under the Workmen's Compensation Act; and what decision he had come to in the matter.—Mr. CHURCHILL answered: There would be considerable difficulties in connexion with the appointment of whole-time medical referees. Under the present system referees are appointed for particular county court circuits, the main part of their duties being to advise in cases in which the judges require their assistance, and the work in any circuit would not be sufficient to occupy a referee's whole time. If the referees were to be whole-time officers, the area for which they would have to be appointed would be so large that a great deal of time would be taken up and expense incurred in travelling, and the arrangement would also be much less convenient to the workmen in the cases where they have to attend on the referee. Another important point is that it is the practice to select the referees as far as possible from doctors engaged in active surgical work, the experience gained in which is of great advantage in deciding on the difficult questions referred to them as referees, and I am doubtful whether I should be able to secure medical men of the same high standing if they were required to give their whole time. I fully agree that the question is one which should be considered, but I think it must stand over till the general inquiry into the Act or possibly the somewhat similar inquiry into the appointment and duties of certifying surgeons is set on foot.

Medical Inspection of School Children.

Mr. CHARLES BATHURST asked the President of the Board of Education whether, in view of the repeated assurances on the part of the Government that adequate grants would be made by Parliament towards the cost entailed by the medical inspection of school children under the Education (Administrative Provisions) Act, 1907, and of the fact that during the last two years the expenditure under this head had been steadily increasing and was already in many cases double the amount originally estimated, and the further fact that the object of medical inspection was of national importance, he would take steps to relieve the local education authorities of part of the increasing burden thrown upon them for this purpose.—Mr. RUNCIMAN said in reply: I have constantly stated in this House and elsewhere that the provision of additional funds from Imperial sources in aid of local expenditure on medical inspection can only be dealt with in connexion with the general question of the relations between Imperial and local taxation which are being considered by a Departmental Committee.

Report of Royal Commission on Tuberculosis.

Sir JOHN LONSDALE asked the President of the Local Government Board what action he proposed to take to give effect to the recommendations of the Royal Commission on Tuberculosis.—Mr. BURNS replied: The report of the Royal Commission, which has just been issued, is receiving my consideration.

Sir JOHN LONSDALE asked the Chief Secretary to the Lord Lieutenant of Ireland whether his attention had been called to the Final Report of the Royal Commission on Tuberculosis, and whether he intended to take any action in Ireland to give effect to the recommendations of the Commission.—Mr. REDMOND BARRY (on behalf of Mr. BIRRELL) replied: There has not yet been time to consider fully the Final Report of the Royal Commission on Tuberculosis with a view to seeing how far its recommendations are applicable to Ireland.

Vaccination and Small-pox.

Mr. BENTHAM asked the President of the Local Government Board whether the increase in the number of children exempted from vaccination through the operation of the Vaccination Acts of 1898 and 1907, and especially since the Act of 1907 came into force, had been accompanied by any noticeable increase in the number of deaths from small-pox in children under 10 years of age.—Mr. BURNS said in reply: There has been but little small-pox in this country since 1907, and up to the end of 1910 no noticeable increase in the deaths of children under 10 from this disease. Figures for 1911 are not yet available.

Mr. ALBERT SMITH asked whether the right honourable gentleman would state the number of cases of small-pox reported in Bury, Stalybridge, Wallasey, and Birmingham this year, with the vaccinal condition of the patients, also the number of deaths, and the vaccinal condition of the victims.—Mr. BURNS answered: In Bury 30 cases of small-pox had occurred, of which none were fatal. The age incidence of these patients cannot be given at present. Eleven of the patients are known to have been unvaccinated, and 16 had been vaccinated in infancy. The Board has no information on the vaccinal condition of the three remaining cases. The Wallasey and Birmingham outbreaks are so recent that no precise information is as yet available. There were 14 cases of small-pox at Stalybridge, of which none were fatal. Of these cases, six were unvaccinated, seven were vaccinated, and one was said to have had a previous attack of small-pox. All the cases under 20 years of age were unvaccinated.

THURSDAY, JULY 20TH.

Milk and Tuberculosis.

Mr. CHARLES BATHURST asked the Parliamentary Secretary to the Board of Agriculture whether, in the light of the final report of the Royal Commission on Human and Animal Tuberculosis, the Board would, as in some continental countries, make it compulsory for all cattle whose milk was sold to the public to be examined periodically to ascertain their freedom from transferable tuberculosis as evidenced by emaciation or visibly tuberculous udders without necessarily employing the sometimes misleading tuberculin test, and thus produce a national register of sound cattle the milk of which could be purchased with confidence by the public.—Sir EDWARD STRACHEY replied: In view of the fact that there are over two million cows in milk in Great Britain the proposal made by the honourable Member is one which might impose a heavy charge upon the local rates and therefore requires a very careful consideration.

National Insurance and Voluntary Hospitals.

Mr. EVELYN CECIL asked the Chancellor of the Exchequer whether he could give any information as to the extent to which members of friendly societies had in the past had medical attendance at voluntary hospitals instead of, or in addition to that of, their club doctor, and whether such claims upon hospitals were likely to be reduced or increased by the National Insurance Bill.—Mr. HOBHOUSE (on behalf of Mr. LLOYD GEORGE) answered: I fear no such information is available. I think the honourable Member is in as good a position as my right honourable friend to estimate the probable effect of the Bill in the direction indicated.

MONDAY, JULY 24TH.

Sleeping Sickness in Uganda.

Mr. MITCHELL THOMSON asked the Secretary of State for the Colonies whether any further report on the measures adopted for the suppression of sleeping sickness in Uganda was in course of preparation, and, if so, when it would be presented; whether the report of the Government entomologist for Uganda, 1909-10, had yet been printed; and, if so, whether he would lay it before Parliament.—Mr. L. HARCOURT replied: No further report is being prepared for presentation to Parliament, as information on all matters in connexion with sleeping sickness is now made accessible to the public through the bulletin which is issued monthly by the Sleeping Sickness Bureau. The report of the Government entomologist for Uganda, 1909-10, has been printed in the Protectorate, and I shall be glad to send a copy of it to the library of the House.

National Insurance Bill Topics.

Mr. HOUSTON asked the Chancellor of the Exchequer whether he was aware that in most of the Continental countries it was illegal for medical practitioners to dispense and for chemists to prescribe; and whether he proposed to adopt the Continental system in the National Insurance Bill.—Mr. HOBHOUSE (on behalf of Mr. LLOYD GEORGE) replied: I do not think an amendment of the law in the direction suggested would be in place in an Insurance Bill.

Mr. HOUSTON asked whether the right honourable gentleman had official information as to the effect of the Sickness Insurance Act of Germany upon the interests of German doctors owing to the small pay or fees they received under it, and showing that the medical treatment given to the insured was thereby prejudicially affected; and, if so, whether he would publish the same; and, if not, whether he would arrange for a Commission of British doctors to be sent to Germany to inquire into, and report upon, the working of the Insurance Act in that country.—Mr. HOBHOUSE answered: The German sickness insurance societies have had their own disputes with the doctor, and as a result are now paying higher fees than formerly, but there is no evidence to show that the medical treatment given to the insured is now unsatisfactory. No doubt the medical service is most efficient where the sickness societies and the doctor are satisfied with the contracts under which it is given.

Indian Medical Service.

Mr. KELLY asked the Under Secretary of State for India whether any posts in the higher grade of the medical service of India, hitherto reserved for military doctors, were now set apart for Indian civil doctors; if so, how many of them had been actually filled so far; and for what reasons were the other posts still closed to Indian medical practitioners.—Mr. MONTAGU replied: The answer to the first part of the question is No; the rest therefore does not arise.

Mr. KELLY asked whether the honourable gentleman was yet able to state the annual cost to the Indian Treasury for the upkeep and education of Europeans and Eurasians for the military assistant surgeon grade; and whether these ranks were still closed to Indian doctors with university and registrable qualifications obtained at their own cost.—Mr. MONTAGU said in reply: The answer to the first part of the question is No, and to the second part Yes.

TUESDAY, JULY 25TH.

Tuberculosis and Milk.

Captain FABER asked the President of the Local Government Board to state whether he could propose legislation to prevent people suffering from consumption from being employed in the milk trade.—Mr. BURNS answered: The subject is under my consideration, but I am not at present prepared to state what action will be taken.

Captain FABER further asked the right honourable gentleman whether he could state, seeing that the Royal Commission on Tuberculosis had reported on the dangers of impure milk, what milk, if any, was coming in from abroad; and whether steps would be taken to closely examine such milk; and what such steps were.—Mr. BURNS said in reply: The importation of fresh milk from abroad has not yet been resumed. When this occurs further series of samples will be taken by the Board's inspectors and will be examined for the presence of impurities, including the tubercle bacillus.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BAINBRIDGE, F. A., M.D., D.P.H. Cantab., has been appointed Professor of Physiology in the University of Durham.

BARTON, G. H., M.R.C.S., L.R.C.P. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Market Rasen District of the county of Lincoln.

BRENTNALL, J. C., M.R.C.S., L.R.C.P., has been appointed House Physician to the Manchester Royal Infirmary.

BROWN, A. MIDDLETON, M.B., Ch.B. Aberd., has been appointed Resident Medical Officer at the Aberdeen Royal Infirmary.

DONALDSON, ROBERT, D.P.H., has been appointed Demonstrator of Pathology in the University of Bristol.

FISHER, A. G. T., L.R.C.P., M.R.C.S., has been appointed Demonstrator of Anatomy in the University of Bristol.

HILL, E. FALKNER, M.B., Ch.B. Vict., has been reappointed Anæsthetist to the Manchester Royal Infirmary.

JEFFERSON, G., F.R.C.S. Eng., has been reappointed Anæsthetist to the Manchester Royal Infirmary.

MOIR, EDWARD, L.S.A. Lond., has been reappointed Anæsthetist to the Manchester Royal Infirmary.

MURRAY, JAMES R., M.B., Ch.B. Aberd., has been appointed Resident Medical Officer at the Aberdeen Royal Infirmary.

RAMSBOTTOM, A., M.D. Vict., has been reappointed an Assistant Director of the Clinical Laboratory at the Manchester Royal Infirmary.

RAY, J. HOWSON, F.R.C.S. Eng., has been appointed Honorary Surgeon to the Manchester Royal Infirmary.

REID, PETER, M.B., Ch.B. Aberd., has been appointed Resident Medical Officer at the Aberdeen Royal Infirmary.

STEELL, GRAHAM, M.D., C.M. Edin., F.R.C.P. Lond., has been appointed Honorary Consulting Physician to the Manchester Royal Infirmary.

WILLIAMSON, R. T., M.D. Lond., F.R.C.P. Lond., has been appointed Honorary Physician to the Manchester Royal Infirmary.

WORMALD, T. L., M.D., B.Hy., D.P.H. Durh., has been appointed Whole-time Medical Officer and Public Vaccinator to the Darlington Union.

WRIGHT, G. A., F.R.C.S. Eng., has been appointed Honorary Consulting Surgeon to the Manchester Royal Infirmary.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ASHTON-UNDER-LYNE, DISTRICT INFIRMARY AND CHILDREN'S HOSPITAL.—Senior House Surgeon. Salary £120 per annum, with board, residence, and laundry.

AYLESBURY, ROYAL BUCKINGHAMSHIRE HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board, lodging, and washing.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—Junior House Surgeon. Salary £70 per annum, with board and residence.

BIRMINGHAM GENERAL HOSPITAL.—House Physician for six months. Salary £50 per annum, with residence, board, and washing.

BRIDGWATER HOSPITAL.—House Surgeon, unmarried, for six months. Salary at rate of £100 per annum, with board, lodging, and washing.

BRIGHTON, HOVE, AND PRESTON DISPENSARY.—Resident Medical Officer, unmarried. Salary £160 per annum, with rooms, attendance, &c.

BRIGHTON, ROYAL SUSSEX COUNTY HOSPITAL.—House Physician, unmarried. Salary £80 per annum, with apartments, board, and laundry.

BUXTON, DERBYSHIRE, DEVONSHIRE HOSPITAL.—Assistant House Surgeon for six months. Salary £70 per annum, with apartments, board, and laundry.

CARLISLE NON-PROVIDENT DISPENSARY.—Resident Medical Officer. Salary £150 per annum, with apartments.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's Inn-road, W.C.—Assistant Surgeon.

CITY OF LONDON LYING-IN HOSPITAL, City-road, E.C.—Physician.

COLCHESTER, ESSEX COUNTY HOSPITAL.—House Physician. Salary £80 per annum, with board, residence, and washing.

COVENTRY AND WARWICKSHIRE HOSPITAL.—Junior House Surgeon. Salary £80 per annum, with rooms, board, washing, and attendance.

DEVONPORT, ROYAL ALBERT HOSPITAL.—Assistant House Surgeon for six months, unmarried. Salary at rate of £50 per annum, with board, apartments, and laundry.

DUMFRIES, CRICHTON ROYAL INSTITUTION.—Pathologist and Clinical Pathologist. Salary £250 per annum, with quarters, board, and laundry.

GLAMORGAN COUNTY COUNCIL.—Medical Officer (female). Salary £250 per annum.

GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—House Surgeon. Salary £100 per annum, with board, residence, and laundry. Also Assistant House Surgeon. Salary £75 per annum, with board, residence, and laundry.

HELLINGLY, EAST SUSSEX COUNTY ASYLUM.—Locum Tenens Assistant Medical Officer for about six weeks. Salary 4 guineas a week, with board, lodging, washing, and attendance.

HEMEL HEMPSTEAD, HERTS, WEST HERTS HOSPITAL.—Resident Medical Officer. Salary £100 per annum, with rooms, board, and washing.

LEEDS PUBLIC DISPENSARY.—Junior Resident Medical Officer. Salary £100 per annum, with board, residence, and washing.

LEICESTER EDUCATION COMMITTEE. — Assistant School Medical Officer. Salary £250 per annum.

LONDON TEMPERANCE HOSPITAL, Hampstead-road, N.W.—Resident Medical Officer. Salary £120 per annum, with board, lodging, and washing. Also Assistant House Surgeon for six months. Salary at rate of £105 per annum.

MACCLESFIELD, CHESHIRE COUNTY ASYLUM, Parkside.—Junior Assistant Medical Officer, unmarried. Salary £150 per annum, with board, apartments, and laundry.

MACCLESFIELD GENERAL INFIRMARY.—Senior House Surgeon. Salary £100 per annum, with board and residence.

MANCHESTER, COUNTY ASYLUM, Prestwich.—Locum Tenens, unmarried, for six to eight weeks. Salary 4 guineas per week, with apartments, board, &c.

MANCHESTER ROYAL INFIRMARY.—Assistant Surgical Officer. Salary £35 per annum.

MIDDLESBROUGH, NORTH RIDING INFIRMARY. — Assistant House Surgeon. Salary £75 per annum, with residence, board, and washing.

NORWICH, NORFOLK AND NORWICH HOSPITAL.—House Surgeon, unmarried. Salary £80 per annum, with board, lodging, and washing.

NOTTINGHAM GENERAL DISPENSARY.—Assistant Resident Surgeon, unmarried. Salary £160 per annum, with apartments, attendance, &c.

NOTTINGHAM GENERAL HOSPITAL.—Assistant House Surgeon. Salary at rate of £100 per annum, with board, lodging, and washing.

OCHILTREE PARISH COUNCIL, Ayrshire.—Medical Officer. Salary £40 per annum.

POPLAR HOSPITAL FOR ACCIDENTS, Poplar, E.—Assistant House Surgeon for six months. Salary at rate of £80 per annum, with board and residence.

PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham, N.—Junior House Physician. Salary £50 per annum, with residence, board, and laundry.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, N.E.—House Surgeon for six months. Salary at rate of £80 per annum, with board, residence, and washing.

ROTHERHAM HOSPITAL AND DISPENSARY.—Assistant House Surgeon. Salary £80 per annum, with board, lodging, and washing.

ROYAL PORTSMOUTH HOSPITAL.—House Physician for six months. Salary £75 per annum, with board, &c.

ST. GEORGE'S UNION INFIRMARY, Fulham-road, S.W.—Second Assistant Medical Officer. Salary £130 per annum, with board, residence, and washing.

ST. MARY'S INFIRMARY, Highgate Hill, N.—Junior Assistant Medical Officer. Salary at rate of £100 per annum, with board and residence.

ST. PANCRAS INFIRMARY (SOUTH) AND WORKHOUSE.—Senior Assistant Medical Superintendent and Senior Assistant Medical Officer. Salary at rate of £135 per annum.

SALFORD UNION INFIRMARY.—Resident Assistant Medical Officer, unmarried. Salary £120 per annum, with apartments, attendance, and rations.

SALISBURY INFIRMARY.—Assistant House Surgeon, unmarried. Salary £50 per annum, with apartments, board, lodging, and washing.

SHEFFIELD ROYAL HOSPITAL.—Assistant House Surgeon and Assistant House Physician, unmarried. Salary £60 each per annum, with board, lodging, and washing.

SHREWSBURY, SALOP AND WENLOCK ASYLUM.—Junior Male Assistant Medical Officer, unmarried. Salary £150 per annum, with board, apartments, washing, &c.

SOUTHAMPTON, ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—House Physician. Salary £100 per annum, with rooms, board, and washing. Also Junior House Surgeon for six months. Salary £60 per annum, with rooms, board, and washing.

SUNDERLAND, MONKWEARMOUTH AND SOUTHWICK HOSPITAL.—House Surgeon. Salary £100 per annum, with board and lodging.

TAUNTON AND SOMERSET HOSPITAL, Taunton.—Resident Assistant House Surgeon for six months. Salary at rate of £70 per annum, with board, lodging, and laundry.

TAUNTON, SOMERSET AND BATH ASYLUM, Cotford.—Assistant Medical Officer, unmarried. Salary £140 per annum, with apartments, board, laundry, &c.

THROAT HOSPITAL, Golden-square, W.—Surgical Registrar.

WALTHAMSTOW, LEYTON, WALTHAMSTOW, AND WANSTEAD CHILDREN'S AND GENERAL HOSPITAL.—Resident House Surgeon. Salary £100 per annum, with board, rooms, and washing.

WARRINGTON INFIRMARY AND DISPENSARY.—Junior House Surgeon. Salary at rate of £100 per annum, with board, lodging, and laundry.

WEST HAM AND EASTERN GENERAL HOSPITAL, Stratford, E.—Junior House Physician. Salary £75 per annum.

WEST HAM UNION WORKHOUSE, Union-road, Leytonstone, N.E.—First Assistant Resident Medical Officer. Salary £150 per annum, with usual allowances.

WESTMINSTER HOSPITAL.—Assistant House Surgeon for two months. Board provided. Also Resident Obstetric Assistant for six months. Board and lodging provided.

WESTON-SUPER-MARE HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board and residence.

WOLVERHAMPTON AND MIDLAND COUNTIES EYE INFIRMARY.—House Surgeon. Salary £80 per annum, with apartments, board, and laundry.

WORCESTER COUNTY AND CITY ASYLUM, Powick.—Third Assistant Medical Officer, unmarried. Salary £140 per annum and all found.

Births, Marriages, and Deaths.

BIRTHS.

COOPER.—On July 20th, at "Lansdowne," Hampton-on-Thames, the wife of Harold Merriman Cooper, M.B. Lond., of a son.

RIDGE.—On July 20th, at Carlton House, Enfield, the wife of R. Leslie Ridge, M.B., B.S. Lond., of a daughter.

SAWYER.—On July 21st, at Farquhar-road, Edgbaston, Birmingham, the wife of James E. H. Sawyer, M.A., M.D., of a son.

MARRIAGES.

KIDD—CURRY.—On July 15th, at St. Lawrence Church, Isle of Wight, Walter Shirley Kidd, M.B., B.S. Lond., M.R.C.S., L.R.C.P., to Philippa Olive, third daughter of Mr. and Mrs. Curry.

DEATHS.

BULSTRODE.—On July 21st, very suddenly, Herbert Timbrell Bulstrode, M.A., M.D. Cantab., D.P.H., &c., Medical Inspector, H.M. Local Government Board.

RIDLEY.—On July 23rd, at The Asylum, Portsmouth, Edward Hope Ridley, M.D. Edin., aged 45 years, Medical Officer at the Asylum.

ROBERTS.—On July 19th, at Chung-King, China, Surgeon R. P. Middleton Roberts, H.M.S. *Teal*. (By Admiralty cable.)

STILES.—On July 19th, at Spalding, Lincolnshire, Henry Tournay Stiles, M.D. St. And., J.P. Holland Division, Lincolnshire, aged 83 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

DEATH FROM ANTHRAX IN A LABORATORY.

UNDER the Workmen's Compensation Act, 1897, a death from anthrax poisoning was first held to be due to an "accident," entitling the dependents of the deceased to compensation, in the case of Brintons, Limited, *v.* Turvey (1905 A.C. 30), when the idea that this could be so was a novel one, and was strongly opposed by Lord Robertson, who delivered a dissentient judgment, expressing disapproval of the view that the inception of any disease could be regarded as due to an "accident." Since then, however, the Act of 1906, which now regulates workmen's compensation, has formally recognised certain industrial diseases as fitting subjects for compensation, and anthrax heads the list in Schedule III., which specifies the diseases and the processes to which the Act applies. The decision in Brintons, Limited, *v.* Turvey benefited workmen to a very limited extent only. The other diseases mentioned in the schedule, such as lead poisoning and ankylostomiasis, had formed the subject of judicial decisions before the Act of 1906 was passed, and it had been held that infection with them was not an accident. A distinction was drawn between anthrax commencing with infection through an abrasion of the skin, a disease attacking its victim with suddenness, and for the first inroad of which a date might be fixed, and diseases the onset of which was gradual, and their inception not to be assigned to a particular date. Anthrax, looked at from this point of view, was an accident; beat knee and conditions due to accumulated doses of lead were not; consequently, one worker's "disease" was a subject for compensation, and that of his neighbour in another equally dangerous process was not. The Act of 1906, however, now removes the unequal conditions created by its predecessor and by the House of Lords' decision, so far as the infection of workmen when engaged upon the specified processes is concerned.

HEALTH AND SANITATION IN WEI-HAI-WEI: OPIUM AND ALCOHOL.

THERE are several points of interest in the report for the year 1910 just received at the Colonial Office from Sir J. H. Stewart Lockhart, K.C.M.G., the Commissioner for the territory of Wei-hai-Wei. This territory, it may be recalled, was leased to Great Britain by China by a convention made on July 1st, 1898. It lies in latitude 37·30 N., longitude 122·10 E. It is in the Chinese province of Shantung, and comprises the island of Liu Kung, all the islands in the Bay of Wei-hai-Wei, and a belt of land ten English miles wide along the entire coast-line, with a total area of 285 square miles. Wei-hai-Wei is a port of call for steamers running to and from the North of China, and there is regular steam communication with the port of Shanghai. The Commissioner records that the general health during the year among both Europeans and Chinese was very good. There was an outbreak of measles on the island and mainland during the spring among the Chinese, but the type was of a mild nature, and few cases proved fatal. There were two cases of scarlet fever, probably imported from Chefoo, and one case of enteric fever. Dysentery was not at all prevalent. One European child died from that disease; all the other cases were of a mild form. Two cases of small-pox occurred. The general vaccination of the inhabitants of the Territory, which is carried out every year throughout the villages, may account to a great extent for the small number of cases of small-pox. The outbreak of plague in Manchuria caused much anxiety towards the end of the year, as many Chinese who emigrate from Wei-hai-Wei to Manchuria are in the habit of returning to their homes to celebrate the Chinese New Year, and it was feared that infection might be introduced through them. As the Territory has a land frontier extending over 34 miles and a coast line over 60 miles in length, to effectively prevent the introduction of disease would require a much larger staff than the Government possesses, and would necessitate the employment of many craft afloat, which are not available. But every precaution under the circumstances was taken, and though the disease spread to Chefoo, distant from Wei-hei-Wei 60 miles by land and 40 miles by sea, and reached other towns between the Territory and Chefoo, Wei-hai-Wei has up to the present time been fortunate to escape with only one case, which was imported and which proved fatal. The patient was nursed by the Lady Superior of the Franciscan Sisters, who all bravely and nobly volunteered their services as nurses in the event of an outbreak of plague. A campaign has been instituted against rats, but to judge from the number caught—only 1200 up to date—it seems that rats are not plentiful in the Territory. All those examined microscopically have been found free from the plague bacillus.

The sanitary condition of Port Edward and the Island continues to be satisfactory. The wells at Port Edward have been covered and fitted with pumps. The Chinese did not at first take kindly to the

pumps, but they now appreciate their convenience. The dairies and abattoir have been carefully inspected, and conservancy arrangements have worked well and been carried out efficiently. The highest monthly barometrical average was that of December, 30·626, and the lowest that of August, 29·354. The highest temperature recorded was 91° for June and July, and the lowest 2° in January and February. Rain and snow fell on 74 days, the annual rainfall being 36·18 in. July was the wettest month, with a rainfall of 10·63 in. In-patients treated during the year in the hospital on the island numbered 16, as compared with 23 in 1909, whilst the out-patients totalled 2277 as compared with 2635 in 1909. At the Port Edward Hospital there were 97 in-patients as compared with 112 in 1909 and 3063 out-patients as compared with 2826 in 1909. There were 123 operations.

During the past year the importation, sale, and smoking of opium were discouraged in every possible way. In 1909 the number of licensed smokers was reduced from 220 to 110, and during 1910 the number was still further reduced to 50. During 1909 the admissions to the refuge established by the Government for those desirous of abandoning the opium habit amounted to 31, whilst during last year they rose to 70, the ages of those admitted ranging from 24 to 74. The police were very active in discovering the illicit smoking and sale of opium, there having been during the year 135 convictions for breaches of the Opium Ordinance. This activity on the part of the police was naturally unpopular among those who have been accustomed to smoke opium, and led to the publication in certain Chinese newspapers printed in Manchuria, Chefoo, and Shanghai of serious libellous charges against the Government. No opium was imported under licence during the year and only one shop was licensed to sell opium. It may be impossible to prevent entirely the smuggling of opium into the Territory across the border or along the coast, but as every step possible is being taken to discourage the use of opium, and as public opinion among the Chinese of Wei-hai-Wei is, if anything, more than ever firmly set against the opium habit, there seems every reason to hope that opium smoking will become even a rarer habit than it is at present. But the diminution in the use of opium seems to be leading to an excessive use of alcohol, and though drunkenness cannot yet be said to be a prevalent vice cases of intoxication are undoubtedly more numerous than in previous years.

The total strength of the police force was three European inspectors, three Chinese sergeants, and 52 constables. The population of the Territory is estimated at 150,000, mostly Chinese, who inhabit 300 villages spread over an area of 285 square miles, so that there is about an average of one policeman to 3000 of the population. The Territory possesses no other local force, with the exception of a few marines, on which it could depend in the case of an emergency. The fact that such a small force is found sufficient for ordinary requirements shows how orderly and well-behaved the inhabitants of the Territory are. Attention has been called to the fact that in the Territory 90 per cent. of the persons who destroy themselves are females, and that as a rule no case of suicide among young people occurs, whilst such cases are said to be increasing in the West. The suicides last year, however, showed a larger proportion of males than usual, and among them was the suicide of a boy aged 15. He appears to have run away from home, but was brought back before he had gone very far. The loss of face caused by his failure to effect his object and the ridicule poured upon him by the village urchins, on account of his enforced return, drove him to hang himself. This case is an illustration of the slight causes which will induce Chinese to take their own lives.

ELECTRO-THERAPEUTIC APPARATUS.

Messrs. W. Watson and Sons of 313, High Holborn, London, W.C., have forwarded us their latest list of apparatus for electro-therapy and diagnosis, which an inspection shows is replete with all modern appliances and appurtenances. Many of the apparatus are made to the design of medical authorities upon the various methods of application. The list includes apparatus for static and sinusoidal currents, radiotherapy, thermotherapy, vibration, electrolysis, radioscopy, faradism, and so forth. The makers themselves have invented some ingenious and useful appliances for treatment.

PROGRESS OF DAVOS.

ACCORDING to the report received at the Foreign Office from Mr. W. R. Huggard, H.M. Consul, the number of British visitors recorded at Davos in 1910 was over 2500, as compared with 2140 in 1909. The numbers of such visitors had previously declined from 3000 in 1899 to about 2000 in 1908. During those same years a marked increase took place in the arrivals from all the other chief nations of Europe. The increase in the number of representatives from other nations is easy to understand. Owing to the excellence of its arrangements Davos offers special advantages both for invalids and for persons in search of outdoor winter sports. Consequent on the compulsory disinfection of rooms that have been occupied by persons suffering from tuberculosis, the danger of tuberculous infection is immensely reduced in Davos, especially in comparison with places where invalids are said not to be taken, but where no precautions are enforced. On this point, which seems to be grasped elsewhere, much misapprehension appears to exist at home. The majority of British subjects resident in the district came to Davos in the first in ance on account of health—their own or that of immediate relatives. A small proportion only earn their livelihood in business or professional occupations. The young Englishman, by his ignorance of languages, is at a disadvantage in obtaining local employment in comparison with the young Swiss or German. The Queen Alexandra Sanatorium, which completed the first year of its active life in November, 1910, is proving of great value for the class for whom it is intended—people of small means affected with curable forms of pulmonary tuberculosis.

Gland.—The sufferer is recommended to consult his medical man. We do not give medical advice.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced for July and August, 1911:—

April–October.—Rome Exhibition (United Italy's Jubilee).
,, 29th–Oct. 26th (Turin).—International Exhibition.
May 3rd–Oct. 31st (Glasgow).—Scottish Exhibition.
,, 6th–Oct. 31st (Dresden).—International Hygiene Exhibition (British Section opens June 14th).
,, 12th–Oct. 31st (London, Crystal Palace).—Festival of Empire Imperial Exhibition. (Profits to King Edward VII. Hospital Fund.)
,, 18th–October 31st (London, Shepherd's Bush).—Coronation Exhibition.
,, 19th–Oct. 31st (London).—Earl's Court Exhibition.
June 1st–August 31st (Squirrels Heath, Romford).—Town Planning and Modern House and Cottage Exhibition.
July 24th–29th (Belfast).—Congress of the Royal Sanitary Institute.
,, 24th–August 2nd (Belfast).—Health Exhibition in connexion with above Congress.
,, 26th–29th (London).—Universal Races Congress.
,, 31st–Aug. 4th (Paris).—Second French Congress of Stomatology.
,, 31st–August 5th (Dijon).—Congress of the French Association for the Advancement of Sciences.
August 1st–6th (Amiens).—Twenty-first French Congress of Alienists and Neurologists.
,, 3rd–5th (London).—British Dental Association, Annual Meeting.
,, 12th–18th (Brussels).—First International Congress on Child Study.
,, 12th–30th.—E.M.I. (Enseignement Médico-mutuel International) Tour in Scandinavia.
,, 15th–21st (Dublin).—Royal Institute of Public Health.
,, 21st–23rd (Larvik).—Fourteenth Norwegian Physicians' Congress.
,, 28th–Sept. 11th (South-East of France).—Eleventh "Voyage d'Etudes Médicales."
,, 30th–Sept. 2nd (Berlin).—Third International Laryngo-Rhinological Congress.
,, 30th–Sept. 6th (Portsmouth).—British Association.
,, 31st and Sept. 1st (Vancouver).—Thirteenth Annual Meeting of the British Columbia Medical Association.

The following journals, magazines, &c., have been received:—Hospital Assistant, Canadian Practitioner, Philippine Journal of Science, Annales des Maladies des Organes Génito-urinaires, Revista Médica del Uruguay, Archives de L'Institut Pasteur de Tunis, Klinik für Psychische und Nervöse Krankheiten, Peru To-day, British Journal of Dermatology, Yale Medical Journal, L'Hygiène, Albany Medical Annals, American Medicine, Medical Times, Encyclopédie Médicale, Revue d'Hygiène, Interstate Medical Journal, Canadian Medical Association Journal, Annali di Medicina Navale e Coloniale.

Medical Diary for the ensuing Week.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Simson: Diseases of Women.

THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (31st).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.).

TUESDAY (1st).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London, (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.) Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.), Royal National Orthopædic (9.30 A.M. and 4 P.M.).

WEDNESDAY (2nd).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (3rd).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal National Orthopædic (9 A.M. and 3.30 P.M.), Royal Ear (2 P.M.), Children Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (4th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Royal National Orthopædic (3.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (5th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. I. of 1911, which was completed with the issue of June 24th, were given in THE LANCET of July 1st.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1911 are now ready. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs. 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

Communications, Letters, &c., have been received from—

A.—Messrs. Allen and Hanburys, Lond.; Anderson's College Medical School, Glasgow, Secretary of; Ayrshire County Council, Ochiltree, Clerk to the; Dr. W. Alexander, Liverpool; Mr. J. W. Arrowsmith, Bristol; Ashton-under-Lyne District Infirmary, Secretary of; Dr. Reginald Alexander, Grosmont.

B.—Bristol University, Clerk to the; Major J. J. Bourke, I.M.S., Calcutta; British Dental Association, Lond., Secretary of; Brighton, Hove, and Preston Dispensary, Secretary of; Messrs. C. Barker and Sons Lond.; Dr. B. N. Burjorjee, Lond.; Dr. W. H. Bishop, Wylam; Sir John Byers, Belfast; Mr. Arthur E. Barker, Lond.; Dr. T. W. Bartlett, Steeple Bumpstead; Dr. Ch. Baümler, Freiburg-i-Br.; British Fire Prevention Committee, Lond., Chairman of.

C.—County Asylum, Bicton Heath, Medical Superintendent of; Messrs. E. Cook and Co., Lond.; Messrs. J. Calder and Co., Bo'ness; Mr. H. A. Collins, Croydon; Children's Country Holidays Fund, Lond.; Dr. Carey Coombs, Clifton; Charity Organisation Society, Lond., Secretary of; Dr. S. Cockburn, Glasgow; Camberwell Board of Guardians, Lond., Clerk to the; Messrs. T. Cook and Son, Lond.; Dr. Adrian Caddy, Calcutta.

D.—Messrs. W. Dawson and Sons, Lond.; Dr. H. B. Day, Cairo; Devonshire Hospital, Buxton, Secretary of; Lieutenant-Colonel C. Donovan, I.M.S., Lyme Regis; Messrs. Dulau and Co., Lond.; P. E. Derrick Advertising Agency, Lond.; *Dental Record*, Lond.; Messrs. B. Davies and Son, Lond.; Mr. J. M. Doman, Liverpool; Mr. A. J. Davy, Lond.

E.—Mr. A. R. Elliott, New York; Messrs. Elder, Dempster and Co., Liverpool; Dr. W. Engelmann, Bad Kreuznach.

F.—Mr. P. Fildes, Lond.; F. J. F.

G.—General Hospital, Birmingham, House Governor of; G. H. C.; Gt. Eastern Railway Co., Lond., Continental Traffic Manager of; Glamorgan County Council, Cardiff, Clerk to the; Grant Medical College, Bombay, Principal of; Dr. Major Greenwood, Lond.; Dr. Alfred Greenwood, Blackburn.

H.—Messrs. Humphrey, Taylor, and Co., Lond.; Captain A. H. Hayes, R.A.M.C., York; Hampton House, Lond., Secretary of; Hoffmann La Roche Chemical Works, Lond.; Holborn Surgical Instrument Co., Lond.

K.—Messrs. D. J. Keymer and Co., Lond.; Dr. Knight, Edinburgh; Messrs. G Kelly and Co., Lond.; Messrs. B. Kühn and Co., Lond.; Messrs. H. S. King and Co., Lond.; Dr. Millard Knowlton, New York; King Edward VII. Sanatorium, Midhurst, Medical Superintendent of; Mr. S. K. Kabraji, Karachi.

L.—Dr. C. Lockyer, Lond.; Liverpool Lint Co., Secretary of; Dr. C. Lillingston, Gorleston-on-Sea; *Leamington Spa Courier*, Editor of; Mr. F. W. Lowndes, Liverpool; Mr. R. Lyle, Liverpool; London and Counties Medical Protection Society, Secretary of; Dr. E. S. London, St. Petersburg; Mr. J. Ernest Lane, Lond.; London School of Tropical Medicine, Secretary of; Leamington, The Town Clerk of.

M.—Miss Isabel Murray, Aberdeen; Manchester Royal Infirmary, Secretary of; *Midland Counties Herald*, Birmingham, Manager of; Macclesfield General Infirmary, Secretary of; Messrs. Macmillan and Co., Lond.; Dr. C. H. McComas, Dorking; Mr. A. Maloine, Paris; Mr. A. N. Marples, Sheffield; Monkwearmouth and Southwick Hospital, Sunderland, Secretary of; Messrs. Mather and Crowther, Lond.; Mr. A. Moxon, Lowestoft; Mr. A. V. Mernes, Birmingham; Dr. E. W. S. Martin, Brithdir.

N.—North Riding Infirmary, Middlesbrough, Secretary of; Northumberland House, Lond., Medical Superintendent of; Mr. M. Neuzerling, Lond.; National Council of Trained Nurses, Lond., Hon. Secretary of.

O.—Dr. J. O'Conor, Buenos Aires; Dr. Bernard O'Connor, Lond.; Mr. Edmund Owen, Lond.

P.—Mr. H. J. Paterson, Lond.; Mr. J. E. Purvis, Cambridge; Messrs. Parke, Davis, and Co., Lond.; *Public Health Journal*, Toronto; Prince of Wales's General Hospital, Lond., Director of; Mr. C. R. M. Pattison, Rathfriland; Dr. T. Frederick Pearse, Calcutta; Dr. O. Penfold, Bendigo; Pasteur Institute of India, Simla, Hon. Secretary of.

R.—Royal South Hants and Southampton Hospital, Secretary of; Rev. W. M. Roberts, Wrexham; Royal National Hospital for Consumption for Ireland, Dublin, Hon. Secretary of; Roborat Co., Lond.; Royal Mail Steam Packet Co.; Royal Westminster Ophthalmic Hospital, Lond.; Messrs. Reynell and Son, Lond.; Dr. J. Herbert Rhodes, Lond.; Dr. John J. Robertson, Portpatrick.

S.—Mr. C. Sibley, Redbourn; Sirdar Rubber Co., Lond.; Mr. F. W. Sears, Lond.; Messrs. A. Spring and Co., Hull; Messrs. W. H. Smith and Son, Birmingham; Society of Apothecaries, Lond., Secretary of; Saarbach's News Exchange, Mainz; Messrs. Savory and Moore, Lond.; Messrs. G. Street and Co., Lond.; Mr. W. W. Strickland, Edolo; Mr. W. Legge Symes, Lond.; Mr. Ernest Stratford, Wellington College Station; St. Catherine Press, Lond.

T.—Mr. Richard Timberg, Lond.; Taunton and Somerset Hospital, Secretary of.

U.—University of London, Principal of; University of Bristol, Registrar of.

V.—Mr. Albert Visetti, Lond.

W.—Mr. A. Wilson, Lond.; Messrs. J. Wright and Sons, Bristol; Western Australia, Lond., Agent-General for; Mrs. Wright, Sheffield; Dr. J. P. Williams, Melalap Tenom; Mr. D. P. D. Wilkie, Edinburgh; Warrington Infirmary, Secretary of; Wolverhampton and Midland Counties Eye Infirmary, Secretary of; Mr. J. B. Ward, Birmingham; Wellcome Physiological Research Laboratories, Lond.; Messrs. W. Watson and Sons, Lond.; Messrs. Woolley, Sons, and Co., Manchester; Mr. H. M. Wheeler, Lond.; Mr. L. Le Warner, Lond.; Professor D. A. Welsh, Sydney.

Letters, each with enclosure, are also acknowledged from—

A.—Ardath Tobacco Co., Lond.; Apollinaris Co., Lond.

B.—Mr. T. H. Burders, Cinderford; Birkenhead and Wirral Children's Hospital, Secretary of; Breconshire Education Committee, Breconshire, Clerk to the; Dr. R. M. Buchanan, Glasgow; Dr. J. M. Bruce, Lond.; Messrs. Bishop, Lond.; The Bristol Myers Co., New York; Messrs. J. Beal and Son, Brighton; Mr. J. J. Bell, Lockerbie; Dr. R. W. Beesley, Bolton; B. J. P. J.; Dr. J. H. Bletsoe, Upminster; Mr. G. P. Butcher, Plymouth; Bristol Royal Hospital for Sick Children, Secretary of.

C.—Chesterfield and North Derbyshire Hospital, Secretary of; The Coppice, Nottingham, Treasurer to the; C. M.; Mr. H. A. Collington, Coventry; Messrs. T. Christy and Co., Lond.; County Asylum, Prestwich, Manchester, Clerk to the; Coventry and Warwickshire Hospital, Secretary of.

D.—Mr. J. B. Davenport, Lond.; Dr. W. T. Dougal, Pittenweem; Mr. V. Darman, Lond.; D. M. E.; D. M. D.

F.—Dr. J. K. Frost, Dorchester; Messrs. Field, Son, and Glasier, Lond.; Fellows Co., New York.

ABSTRACT OF

The Edward Jenner Lecture

ON

SCHOOL HEALTH.

Delivered at the Medical School of St. George's Hospital (University of London),

BY F. E. FREMANTLE, M.B. OXON., F.R.C.P. LOND., F.R.C.S. ENG., D.P.H.,
COUNTY MEDICAL OFFICER FOR HERTFORDSHIRE.

[AFTER pointing out that school children are entrusted to the State for a large part of their malleable life and that consequently the State has both a responsibility and an opportunity of moulding its future citizens in accordance with the rules of health and medical experience; that the science of public health has changed its position, enlarged its field of view and scope of action; and epitomising the history of the rise of school medicine, Mr. Fremantle continued:]

It was in Wiesbaden that our English system of attention to school health had its origin, attention being there focussed on the child rather than on its surroundings, and provision being made for thorough physical examination of every child on admission and in the third, fifth, and eighth years of school life, as well as for the detection of infectious disease and the inspection of premises. In 1898 this method was adopted in the towns throughout Germany, and by the time it was transplanted to Great Britain medical inspection had been established in most civilised countries of the world, including North and South American States, and since 1898 as a complete system in Japan.

The duty of inspecting all children in English public elementary schools was enacted by the Education (Administrative Provisions) Bill, 1907, which gave education authorities also the power to provide treatment of defects. The Board of Education is responsible for supervising the work. The principles of action that guide the Board are in a less formal way described in the annual report of Sir George Newman, chief medical officer to the Board, which is published towards the end of every year. I would strongly advise your expending 8½*d.* on the report for 1908, which contains the circulars of the Board and the provisions of the Code relating to this subject, in addition to an attractive account of the first reports of the work from all parts of the country.

OBJECTS AND PRINCIPLES OF MEDICAL INSPECTION.

In these circulars the Board lays it down that it aims not at an anthropometric survey but at the physical improvement, and as a corollary at the mental and moral improvement, of future generations. The broad requirements of a healthy life are few and elementary, but essential and economical, both to the individual and to the community, by reason of the consequent decrease of inefficiency and of destitution in after life. It was shown that the health of school and of home go together, and that in this matter the local education and the local sanitary authorities should coöperate.

The system thus inaugurated has been criticised as providing only for inspection of defects without providing for their cure. This, however, is sound. The first need is a knowledge of the nature and extent of the defects to be met; the second need is the distribution of such information to the parents, on whom the direct responsibility should continue to rest; the third need is the stimulation of charity and of every existing agency to undertake the treatment of these defects; the fourth need is a knowledge of the cases remaining untreated and the reasons for such neglect. Then, and then only, will it be possible to present a case for providing means of treatment; and then it will be far better to proceed by an extension of existing methods and principles of medical provision rather than to inaugurate a new system of school clinics, as they are called, for this particular purpose.

Medical inspection, then, is the basis of the system, a routine inspection at certain stated periods in every child's life and a further periodic inspection whenever the school doctor or the teacher thinks it advisable. But this inspection is only the framework. On it must be built up the whole system of physical education, interwoven as it must be with the existing system of moral and mental education. The school teacher, therefore, must be trained and accustomed to consider the bodily health in every detail of school life; and the school doctor must hold himself responsible that due attention is paid to the rules and conditions and habits of health at every turn of the educational machine. It is no mere inspector that is required, but a family doctor to the school, with a "cure" of the bodies comparable to the "cure" of souls for which his clerical brother is responsible.

The main objects, then, are three:—1. The health and future ability of each child. 2. The healthy influence of each child on its neighbour. 3. A statistical record by which to compare the health of different schools and communities or of different years and periods, and so to arrive at the effect of different social conditions in promoting or retarding health.

The main principles to be observed are therefore as follows:—1. The gradual installation of the school doctor as the general and responsible guardian of the school health. 2. The gradual installation of the school teacher as the daily inspector of the children's health, and as the prime agent in the inculcation, both by reason and habit, of school hygiene. 3. Continuity of medical inspection and record throughout the school life of each child. 4. A high degree of clinical experience, public spirit, and personal authority in the medical inspector. 5. Intimate connexion between those in charge of the child's health at school (the head-teacher and medical inspector) and those at home (parents and sanitary authority). 6. Sufficient participation by those in charge of school health in the whole work of the educational machine. 7. Accuracy, a uniform common-sense standard, and an efficient method of recording the facts observed; care in their compilation; caution in the deduction of results, and wisdom in the presentation both of facts and conclusions to the authority and to the public.

ORGANISATION OF MEDICAL INSPECTION.

By the end of 1908, 307 out of 328 local education authorities in England and Wales had already appointed school medical officers officially recognised by the Board of Education; 224 were medical officers of health. The Board, however, will recognise only one titular school medical officer for each local education area. The question, especially for counties, was then how to organise the work. Considerable difference must obviously be made between urban and rural areas. The intensity and the publicity of the problem and of the results in towns attract attention; but in this, as in every branch of public health work, it is in the villages that the causes of any condition can be traced to their sources and most easily remedied.

The special characteristics of rural conditions in this respect are:—1. The greater distances, allowing less work to be done in any one particular day. 2. The existence of fewer medical men, the only specialists among them being those that hold whole-time appointments as medical officers of health; while, on the other hand, the general medical practitioners have wider general interests and experience than their colleagues in the towns; they are a more permanent and integral part of the community, and their view is nearer to that of the intelligent laymen. 3. The school teachers are as a rule less highly trained, but know their children, parents, homes, and surroundings more intimately, and retain their influence over them after they have left the school. 4. The rural schools are smaller. 5 The village nurse, with her year's training in midwifery and sick nursing, is becoming as integral a part of rural life as the schoolmaster, doctor, or priest.

The methods actually adopted for the work in areas where the (chief) school medical officer requires assistance are: (*a*) By whole-time inspectors *ad hoc*, at a salary of £250 a year; these, however, if satisfactory, will be constantly changing; they are mere inspectors, unconnected with the Public Health Service, and narrowed by the very special nature and strict limits of their work. (*b*) By unofficial general practitioners, as in London, where quarter-time assistants are engaged. They, too, are unconnected with the Public Health Services, and are strangers to all concerned.

(*c*) In rural areas by the Poor-law doctors. They are conversant with the homes of the people and offer the great advantage of combining the work of prevention and cure. But they are as yet unconnected with the Public Health Service; they include many of the least competent practitioners, and their number intensifies the difficulty of administration. (*d*) By the district medical officers of health. This is the system adopted in Hertfordshire; against certain minor drawbacks it combines the advantages of local knowledge, permanence, broad interests, and full connexion with the Public Health Service.

The payment in the Hertfordshire system depends on several factors as follows:—(1) 1*s*. 6*d*. for each child inspected in due course, on receipt of a copy of the record-card at the county office. (2) Capitation fee of 3*d*. a year for every child on the books, in return for other work inevitably involved. (3) Travelling fee of 5*s*. a visit, up to four visits in the year, to schools outside the towns in which the officers reside. (4) Postage fee of 1*s*. a year for each school. This payment appears to be fair and satisfactory both to the officers and to the authority, and may be recommended for general adoption.

It is necessary to emphasise the importance of thus uniting the public health and school health services; for in the greater part of the country this ideal, laid down as we have seen by the Inter-Departmental Committee and by the Board of Education, has become a dead letter, and the separation of the services, except for the nominal supervision of the school medical officer, has been condoned and even commended by the Board. Before long it may be that the councils of county boroughs and counties will be the sole local authorities for all purposes. Then, it is to be hoped, there will be no difficulty in uniting the various local public medical services into one comprehensive system under a single chief medical officer. Then the duties should be so distributed that, as far as possible, the school work coincides with the public health work of every area.

DUTIES OF SCHOOL DOCTORS.

Let us, then, briefly run through the duties of the schoo doctor, as I prefer to call him, rather than use the cold, formal title of medical officer. The actual system in force in Hertfordshire will serve as a type, recognising that the details depend on a variety of circumstances and a variety of personalities, corporate and individual. Each area has to work out its own salvation, within the prescribed limits, as it thinks best. No one system can be adopted ready-made in every particular, in any other area than that in which it has developed.

1. *Routine inspections.*—Every child is inspected on admission and in the eighth and eleventh years after the year of its birth. Children are therefore inspected at 3–5 (or later), 7–9, and 10–12. The assistant school medical officer sends a postcard to the head teacher, giving a week's notice of his intended visit; and the teacher sends notice to the parents of children not previously inspected, inviting their presence. This also gives them the opportunity of sending a written refusal to allow inspection. Of nearly 14,000 children due for inspection last year, the parents of 44, or 0·3 per cent., refused inspection. Under the Children Act, 1908, however, the doctor has power, even in these cases, to inspect the cleanliness of person and clothing, and I have delegated similar powers to the school nurses. The inspection must take place in school hours—i.e., generally between 9 and 12 or 2 and 4, and on school premises unless special sanction of the Board is obtained for the use of other premises close by. A schoolroom has generally to be used for the purpose and the children from that room are crowded into another room or turned out into the playground. The apparatus consists of a good steel-yard weighing-machine, a measuring standard fixed usually for the occasion to the wall, and test-type at a distance of 6 metres (21 feet), with the doctor's own stethoscope and tongue-depressor. For this he often brings a packet of wooden gardeners' labels, using one end for each mouth, and throws them into the fire after use. It is not a detailed clinical examination, but a physiological inspection to find out the chief defects. Results are recorded on cards kept at the school, copies being sent to the county medical office.

2. *Special inspections* are at the same time made, either of children previously inspected and kept under observation or of children to whom attention is drawn by the teacher.

3. *The apparatus* is in general charge of the doctor, to whom the teacher is responsible for its care, the two county inspectors of weights and measures being held responsible for the condition of the weighing machines.

4. *The sanitary condition of premises* has to be observed and defects noted on a sheet form provided for each school, on which are printed all the items of structure and fittings throughout the premises, and columns are left for notes of defects and improvement year after year. Here it is of first importance to note the signs of cleanliness and proper use of every part—e.g., the opening of windows, the supply of drinking water, the use made of closets.

5. *The teachers*, and especially the head teachers, must be encouraged to pay attention to health and physical development at every turn of school life; and, as most of them have received no instruction in the subject, it rests with the school doctor to show them in what way the principles are to be attained. At every visit the doctor should find an opportunity to discuss some health question with the head teacher without appearing to offer instruction.

6. *The whole curriculum* should be surveyed by the doctor with a view to its bearing on school health. More especially will his attention be directed to the teaching of hygiene, to physical drill, to mental strain; but his influence may, and should, eventually reach to the full extent of the curriculum.

7. Much *correspondence* and many personal interviews are involved by every phase of this work—with parents, teachers, and attendance officers; with school managers and subcommittees; with the education, sanitary, and Poor-law authorities; and with charitable persons and agencies. The more that this can be done in person rather than by post the better; tact is of first importance, and the district medical officer of health is in a far better position to carry out these duties, and so influence the general population in the way of health, than the whole-time inspector for the country school.

8. *Cases should be followed up* to their homes in order that home conditions, which are often mainly responsible for defects, may be discovered, parents interested, and the children assisted to secure treatment.

9. Once every year the school doctors must supply an account of their work done during the year *for the annual report*, which the chief school medical officer has to prepare for the information of his authority and of the Board of Education.

RECORDS OF MEDICAL INSPECTION.

It is impossible here to indicate the results obtained from these records. They provide, it is obvious, for a complete physiological survey of the whole elementary school population of the country, and the results, carefully handled, should be of national importance.

So far our figures of height and weight suggest that the town children belong to a better physical stock, although greater physical development occurs in the villages than in the towns; and that in increased degree the physical stock of Hertfordshire is less good than that of London, but that by the age of 12 the Hertfordshire children have passed those of London both in height and weight. Equally interesting figures—likely to be of the utmost profit to social reformers—are those derived in the comparison of clothing and footgear, nutrition, and cleanliness; while more specifically medical problems are suggested by the fewer defects of the teeth and of vision in rural areas at the later ages.

It is sufficient, finally, to refer to the total figures which show that only 6 per cent. of the children have perfect teeth; that 12 per cent. appear to have adenoids, 13 per cent. have defective vision, 13 per cent. have unclean or verminous heads, 44 per cent. are defectively vaccinated, while only 0·2 per cent. are found suffering in any way from tuberculosis.

The greatest possible care must be taken in the collection, recording, and analysing of these records, still more in deducing the causes and cure of the defects set forth. With such care the study is likely to be the essential and inevitable forerunner of measures to enhance very greatly the national physique.

SYSTEMS OF TREATMENT.

What are these measures to be? In the first place, there are the absolute mental or physical cripples, the blind and

deaf, the imbecile and the mentally defective. For these cases London and the other large towns have special schools, both residential and day. They also have special schools or classes for tuberculous, paralysed, and other crippled children, who are taken there in a special ambulance carriage. Special open-air schools are also provided in the London suburbs, to which anæmic and ill-nourished children are sent for a season. For the defectives, in county areas reliance has usually to be put on residential schools belonging to private charities, to which the education authorities subscribe for so many beds. Many authorities now have, or are building, their own homes for the mentally defective and for the epileptic, who, however, must be educated in separate institutions from one another. The parents' consent is necessary, and a weekly parental contribution, where means will allow, is usually required.

For the treatment of curable defects the authority is allowed, subject to the sanction of the Board of Education, but is not obliged, to undertake treatment. The following are the alternatives:—

1. *School clinics*, or out-patient hospitals, established for the purpose. Eleven of these were sanctioned for the year 1909–10, including the purely dental clinic at Cambridge. For dental work there is need of some such institution. But merely for the treatment of skin and eye diseases and of adenoids it is difficult to justify such an establishment, if it is to be decently equipped and arranged. Occasionally, as at Hampstead, Wandsworth, and Norwood, such a clinic is provided by the medical profession in the locality, who together contract with the authority to staff and maintain it.

2. *Use of existing hospitals*, either voluntary or in return for a subsidy. London has such arrangements with three voluntary and 14 subsidised hospitals, adequate payment being made for the clinical assistants and for all expenses incurred. This arrangement is not generally approved by the medical profession, as it increases hospital practice and the privileged practice of the staff; it is not wholly satisfactory to the County Council, as the hospitals stipulate for complete freedom of action. Nevertheless, where the hospital almoners play their part well and refuse treatment to children whose parents can pay, the advantages of this method for the time being are obvious.

3. *Recognised surgeries* are proposed by the British Medical Association for county areas, in which a scale of fees would be payable to most medical men in these areas, after official appointment, for treatment of defects in their surgeries.

4. *School nurses only.*—In contrast to other suggestions the authority may decline to establish a new scheme of treatment. Parents should secure treatment, they may say, under present conditions at the hands of medical practitioners or charitable hospitals, the Poor-law having provided for medical treatment out of the rates for those who cannot afford payment. All that is then necessary is a system of nursing to persuade the parents of what is necessary and to see that it is carried out. In county districts, at least, this should be effected by a subsidy to local nursing associations for the employment of the existing village nurses, preferably through the medium of a county nursing association, which can supply the supervision and instruction necessary. Coördination of nursing in a single system for each county is thus also promoted.

This last system of coping with the physical defects of school-life is certainly at present inadequate. The Poor-law has not yet provided out-patient departments for this kind of work. But reform of the State medical services is at hand, and rather than create new institutions it is best for us to make the utmost use of existing institutions, and so show the need, in reforming the Poor-law or developing the system of State insurance, of creating machinery to deal with these cases of minor ailment in school children as an essential duty of a comprehensive and unified State medical service.

I hope, gentlemen, you will throw yourselves into this school work with zest. It is a fundamental factor in the public health and offers a prospect of immense benefit to national prosperity and happiness, which are primarily dependent on the national health, especially in the rising generation, and especially, therefore, in the public elementary schools.

ON CANCER.

CANCER REGARDED AS AN ADAPTIVE RESPONSE ON THE PART OF CERTAIN CELLS OR CELL GROUPS TO ENVIRONMENTAL CHANGE, AND AS THE RESULT OF A PROCESS OF VARIATION AND SELECTION OF AN "INTER-" OR "INTRA-" CELLULAR KIND.

BY C. J. BOND, F.R.C.S. ENG.,
SENIOR SURGEON TO THE LEICESTER INFIRMARY.

THE object of the following inquiry is to analyse, as far as they are known, the conditions under which the new cell characters which we associate with cancer arise in somatic cells; to inquire whether the three conditions which accompany variation and selection among other organisms are also concerned in the evolution of cancer. These are: (1) struggle for existence among cells; (2) cell proliferation; and (3) cell destruction.

We must start with the fundamental truth that every adaptive response made by cells to environmental change is the outcome of the interaction of two factors—environmental stimulus on the one hand and cell potentiality on the other. The response may be "direct"—that is to say, the conditions under which the reaction occurs may be comparatively simple, and the new cell character may arise in direct response to the changed conditions. Or the conditions of the response may be so complex as to elude analysis, and the new characters may appear to arise just as the so-called spontaneous variations arise in germ cells without any direct reference to the environmental change. In both cases alike, however—in the "direct" form of use acquirement and in the "indirect" form of innate variation—the process is essentially the same. It is one of variation and selection among individual units exposed to changed conditions. These units may be individual cells or they may be represented by the physiologically differentiated parts which compose the cells. In the one case selection will be on an *inter*-cellular, in the other on an *intra*-cellular plane.

Any consideration of the cancer problem must therefore include a consideration of the conditions under which certain cells (as the result of the interaction of environmental stimulus with cell potentiality) exhibit certain characters which enable them to live and multiply more freely under changed surroundings. In this sense, therefore, cancer may be regarded as an adaptive response, and it becomes important to ascertain the conditions under which the response is made.

If we recall the different varieties of cells which together form the individual soma of any multi-cellular organism belonging to one of the higher types, we shall recognise that, from the point of view of cell environment, they may be divided into two great groups: The connective tissue or hylic group (Adami) on the one hand, and the epithelial or lepidic group (Adami) on the other; or from the "adaptation" point of view the group without, and the group with external world relationships. As regards the individual cells of the first or hylic group the cell environment is a dual one; it is made up of the nutrient medium and the activities of neighbouring cells, and in a remoter degree of all the remaining cells which compose the organism. But for the epithelial cell the environment is a threefold one. In addition to the nutrient medium and the activities of neighbouring cells, it embraces also the stimuli of the external world or that portion of it with which the cell is brought into more immediate relationship.

Even those cell aggregates which, by downgrowth or outgrowth from the surface layers, form the glandular organs, although they have lost touch with many external stimuli, they still remain in potential or actual communication with the outside world. For even in their case the mucous channels, the ducts by which their secretions reach the surfaces of the body, serve as channels of communication between these cells and the exterior, and the temporary stasis of contents which frequently and intermittently occurs in these ducts, associated as it is with backward mucous currents, acquires additional importance from our present point of view.[1] The internal secretion of the ductless glands like the thyroid is in reality an external secretion retained under pressure and

[1] Address in Surgery, Bond, THE LANCET, July 29th, 1905, p. 275.

re-absorbed, and is associated with a primary origin of these glands from the epithelial or lepidic cell group having external world relationships.

The endothelial and mesothelial cells, connecting as they do the hylic with the lepidic group, stand in an intermediate position. They line the blood-containing and the lymph-containing spaces and body cavities, and their environment comprises the nutrient medium, blood or lymph, the activities of neighbouring and other cells, and such external influences as reach them from the outside world in the shape of food material, micro-organisms, and chemical substances contained in the blood or lymph streams.

The germ cells form another group having peculiar environmental relations. By virtue of their normal capacity for migration and their abnormal liability to prenatal displacement at different periods of their life-history they establish relations with different kinds of body cells, with body cavities, and with the outside world, and, like the somatic cells of different types among which they grow, they give rise to tumours of a special kind, the teratomata, which include also malignant and benign types.

Thus we can divide the body cells, and the blastomata which spring from them, into two large groups: those in which the external world forms an actual or potential factor in the cell environment, and those in which the environment is limited to the nutrient medium bathing the cells, and the activities of neighbouring cells and those which compose the rest of organism. The latter factor will, of course, be reversed in the two groups. In the case of the epithelial cell it will primarily consist of mesoblastic cells, and in the connective tissue group it will consist of epithelial cells or mesoblastic cells of another subtype.

In thus classifying cells and the new growths which arise from them according to their environmental relationships we must remember that only the ordinary environmental factors normal to the cell in each case are thus included. Under abnormal conditions many outside influences may affect the cells of both groups, both those normally exposed to, and those normally excluded from, contact with the exterior of the body. For instance, wounds, solutions of continuity of surface of all kinds, allow contact with, and the entrance of, foreign substances in the shape of micro-organisms and their secretions. The physical stimuli of light, heat, sound, contact, X ray vibrations, radio-active substances, all these and many other agencies may, under special circumstances, bring about environmental changes and exercise an influence on all kinds of body cells.

Bearing these facts in mind, we are now in a position to examine the conditions under which, as far as they are known, the cells of both groups originate those new characters which are associated with tumour formation, malignant and benign. It is evident that any attempt to explain the cancer problem, as an adaptive reaction if it is to be satisfactory, and any attempt to classify the diversified types of blastomata, if it is to be complete, must include a detailed description of the effect of every environmental factor in relation to each normal and abnormal cell potentiality, hereditary and acquired, in the cell group in which the new characters arise. Such a proceeding is manifestly impossible. But this fact does not render useless a partial analysis of the conditions under which cancer occurs in one—for instance, the epithelial—group of cells. Such an inquiry if conducted on sound principles may throw light on the larger problem.

Following out this conception of the threefold nature of the environment of the normal epithelial cell, the cancer problem will mean for us a consideration of the conditions under which the cancer characters arise in epithelial cells in response to some change in one or all of these three environmental factors. Moreover, a careful study of the differences which distinguish the cancerous from the normal epithelial cell shows that these differences can also be grouped in relation to these same three environmental factors.

I. *Nutritional Factor.*

Let us take the nutritional factor first. The epithelial cancer cell exhibits a greater capacity for absorbing and assimilating nutrient material than the normal epithelial cell. Not only so, but in proportion as the normal cell approximates to the cancer type, in such proportion it acquires a larger cytoplasmic surface area capable of assimilating nutrient material. This fact will become apparent when we remember that the fully grown functionally active epithelial cell which covers the skin surface, or lines a mucous cavity, or gland acinus, or gland duct, presents a free cytoplasmic surface to the exterior. It is by this surface that the external secretion which it elaborates reaches the exterior. This surface is not available for the assimilation of nourishment from the blood or lymph stream. It is only available for the ingestion of such nutrient material or foreign substances as may reach the cell from the outside world.

Now in proportion as the cancer cell grows away from its normal relationship to the external world, in proportion as it tends to lead an independent existence, and to grow and multiply amongst the neighbouring mesoblastic cells, in proportion, moreover, as it ceases to pour out external secretion and to carry on normal functions, in such proportion it ceases to exhibit the normal differentiation of cytoplasmic substance into absorbing and secreting surfaces, and develops assimilative and absorbing capacities over its whole cell surface. Moreover, as we should expect, this retrogressive change is most marked in the peripherally placed cells of primary and the cells of secondary growths.

This disturbance of the normal relationship between secreting and absorbing surfaces is characteristic of cancer of the epithelial type, but, as we shall see later, it is not characteristic of cancer of the connective-tissue type. This is probably due to the fact that the normal connective-tissue cell has no external world factor in its environment, consequently the blastomata which originate from these cells do not exhibit changes in reference to it, while coincidently with this distinction we find, also, that external stimuli are more closely associated with the origin of cancer than with the origin of sarcoma.

It is interesting to note that cancers of the breast of the colloid type present only a slight degree of malignancy, and the question arises whether the low degree of malignancy may not be associated with the retention on the part of the epithelial cells which form such growths of some capacity of forming an external secretion which, under the conditions of retention present, brings about the degeneration of the cells.

But whatever may be the nature of the secretory change which distinguishes the cancer from the normal epithelial cell, it is certain that a greatly increased capacity for vegetative growth is one of the distinguishing features of the cancer cell. Vegetative growth means increased assimilation of nourishment, and this in the large epithelial cancer cell means increase in area of cytoplasmic surface capable of assimilation. Moreover, the rapidly recurring cell division characteristic of the cancer cell is closely associated with this recurring alteration of relationship between bulk of cell substance and area of assimilating surface.

There are certain facts which suggest that this increased assimilative capacity in the cancer cell is a further development of a capacity possessed in lesser degree by the normal epithelial cell. Thus, Fischer found that the subcutaneous injection of Scharlach R in olive oil beneath the corium of the rabbit's ear stimulated the epithelial cells of the epidermis, and produced in them a downward growth in the direction of the substance so injected. This experiment demonstrates the influence of an environmental change of a nutritional kind in initiating an adaptive response on the part of epithelial cells exposed to it. In this case the chemiotactic capacity displayed lies within the normal limits of epithelial cell potentiality, while in the case of the cancer cell it extends beyond these limits.

II. *Neighbouring Cell Factor.*

We must now consider the second factor in the environment of the epithelial cell: the physical and chemical activities of the neighbouring cells and of the cells which compose the organism. In response to this "other cell" influence the epithelial cancer cell exhibits capacities of an adaptive kind, of a kind which favours its own vegetative growth and cell division at the expense of the growth and functional activity of the neighbouring cells of different type. The aim (if we may so express it) of the epithelial cancer cell is to stimulate the surrounding mesoblastic cells to a reactionary growth, sufficiently active to provide the necessary vascular support, but not so active or so fully organised as to threaten by fibrous encapsulation the nutrition of the cancer cells. This growth relationship between cell-groups of different structural and functional types (which in normal

development is so delicately balanced) is disturbed by the great vegetative activity of the cancer cell.

As I suggested[2] in 1886, the capsule of any glandular epithelial organ may be regarded as the expression of a reactionary growth on the part of mesoblastic cells to the encroachments made upon them by the growth of cells or cell-groups of a different germ layer origin. The growth limit of any glandular organ is determined, within certain hereditary limits, by the opposition offered by neighbouring mesoblastic cells to the growth of the epithelial cells which compose the organ. The capsule is the result of this adaptive reaction on the part of the mesoblast cells, and the exact stage in ontological development at which a supporting and nourishing stroma becomes a limiting fibrous capsule is a matter of mutual adjustment between the hereditary capacity of epithelial cell growth and division, and the hereditary capacity of connective-tissue cell growth and division. It is only in some such process of mutual adjustment between the activities of cell-groups of different types that we can conceive of the orderly development of the organs and tissues of the multicellular organism as rendered possible.

We may extend this conception of the relationship between supporting stroma and enveloping capsule to the problem of the growth of neoplasms, malignant and benign. The growth of a benign tumour of the lepidic and hylic type is limited by a fibrous investment of connective-tissue growth analogous to the capsule of a normal organ. It is formed by the surrounding cells of different type or sub-type. In this case, also, the stroma, which serves as a support and nourishing medium for the cells of the tumour, becomes at its surface a more fully developed fibrous capsule. The cells of the definitely benign growth exercise the activities of normal tissue cells of corresponding type towards the surrounding mesoblast cells, and the reaction made by the mesoblast cells resembles that made to normal tissue cells.

It is very different with the cells of the malignant growth. The balance of mutual growth resistance has been disturbed. Having lost the capacity for normal cell division, conformable with the exercise of normal function, and the interests of the surrounding tissues and the body as a whole, the cancer cell has gained power to undergo cell division irrespective of the interests of the surrounding tissues and the body as a whole, and conformable only with the fullest exercise of its own vegetative activity. And this adaptive process requires the exercise of a very delicate influence on the part of a cancer cell over the growth activities of the surrounding mesoblast cells. Stimulation above or below the right level results in the development of a limiting and protective capsule on the one hand, or an inadequate nutritive stroma formation on the other. Further, the exercise of this specific influence by the cancer cell induces in the mesoblast cells abnormal growth along the same direction as that in which the cancer cell has itself varied away from the normal epithelial cell. And this result is brought about probably by a bio-chemical rather than by any sperm-like influence on the part of the cancer cell.

The process of stroma formation is a lowly organised phase of the same process of cell division and cell organisation by which, when carried to a higher level of tissue development, the mesoblast cells are enabled to resist the encroaching growth of the cancer cells. Thus Ehrlich and Bashford have shown that under certain conditions of repeated transplantation, the epithelial cells of mouse cancer may evolve a capacity to influence the reactionary growth of the mesoblast cells and reduce it to even a lower level of tissue development. These observers have found that under such conditions the portion of mammary cancer so transplanted may induce in the connective tissue in which it is embedded a low-grade growth indistinguishable histologically from sarcoma. These facts confirm the suggestion that the capacity of the epithelial cancer cell to influence the growth of mesoblastic cells in abnormal directions is an excess variation of a capacity normally possessed in a lesser degree by epithelial cells.

III. *External World Factor.*

We may now consider the third or external world factor in the epithelial cell environment, and try to ascertain in what way, in regard to it, the cancer cell has varied away from the normal epithelial cell.

The two chief adaptations exhibited by epithelial and gland cells in relation to external world stimuli are (1) elaboration of external secretions and (2) deposition of formed material of a protective kind. The epithelial cancer cell shows a diminished capacity for the elaboration and discharge of the secretions formed by normal cells of the type to which it belongs. This peculiarity, as in the case of other cancer characters, is a relative change. Thus the cells of malignant adenomata secrete some mucus. Müller long ago detected casein in the cells of mammary cancer; Waring has found pepsin in gastric, and trypsin in pancreatic cancer tumours. Other observers have detected bile in the metastatic growths formed by liver cancer.

Allowing, however, for these observations, the fact remains that the external secretions elaborated by cancer cells differ quantitatively and qualitatively from the secretions formed by normal epithelial cells of a corresponding type. In fact, the degree to which the cancer cell has lost the power to elaborate normal external secretion is a direct index of its malignancy, and with this decreased capacity in one direction goes increased capacity for vegetative growth, and the point that I particularly wish to emphasise is the desirability of considering this peculiar loss of functional capacity in relation with the special factor in the environment (the external stimuli) with which it is under normal conditions associated.

But besides elaborating external secretions, epithelial surface cells react to the influences of the external world in another way, and that is by the formation and deposition, either within the limits of the growing cell or outside these limits, of material of a protective kind. Thus the surface cells of epidermal tissues undergo keratinous change. And other examples of cytoplasmic differentiation of a similar kind could be mentioned. Now the cells of a squamous-celled epithelioma do not present the same degree of keratinisation as that shown by normal squamous epithelial cells. This is especially noticeable in the cells composing the secondary deposits formed by squamous epithelioma. Neither do such cells present the regular cogwheel interdigitations found in normal cells. It would be interesting to know whether cilia are present in cancer cells arising in ciliated epithelium, and, if so, whether they are found in the cells forming the metastatic deposits found in such tumours.

We may recapitulate this enumeration of the adaptive characters shown by epithelial cancer cells to the three primary factors of epithelial cell environment by saying that the characters associated with the cancer habit indicate diminished or defective adaptation to the external world factor, and increased adaptation to the nutritional factor, and to the activities of other cells. A fully developed and functionally active epithelial cell flourishes with one cell surface attached to the underlying cells and bathed with nutrient lymph, while the other surface is free and exposed to external influences, whereas the epithelial cancer cell grows best with all its surfaces brought into relationship with the activities of neighbouring cells, and bathed in nutrient material of a lymph-like nature. Such, then, is the cancer process viewed as an adaptive response on the part of epithelial cancer cells.

Effect of Bodily Conditions.

Let us now consider epithelial cancer from the standpoint of the individual organism and consider the bodily conditions which are supposed to favour its origin.

Age of individual.—Individual age on closer analysis means relative senility of the different epithelial tissues of different types in the same individual. Cancer tends to originate in epithelial tissues that are growing old. But age means physiologically, number of previous generations passed through by the cells composing the particular tissue in question. And tissues which are nearing, or have reached, the hereditary limit of capacity for normal function and normal metabolism have, as a rule, passed through a larger number of cell generations than tissues which are still active functionally.

The question, therefore, is, What are the external or internal influences (apart from the length of life of the individual as a whole) which tend to induce abnormally rapid cell division in, and consequently ageing of, epithelial tissues? Among such influences we must include mechanical and chemical irritation, X rays, alcohol, soot, arsenic, betel nut, tobacco, clay pipes: all these are chronic irritants. And in so far as chronic irritation acts as a predisposing

[2] Transactions of the Leicester Medical Society, 1886.

cause of epithelial cancer, it does so by disturbing the nutrition of the epithelial cell and by causing rapid cell division, and in this way by bringing about cell senility.

The same senile influence is exerted on epithelial tissue by the frequently repeated exercise under special abnormal conditions of otherwise normal physiological functions. Thus cancer is more frequent in the uterus and mammæ of women who have borne and suckled children than in women whose organs have not passed through such cycles of increased and diminished cell growth, cell division, and cell destruction. These last three processes are the three conditions which favour the occurrence of variation and selection among organisms exposed to them, and of the abnormal conditions associated with their exercise, stasis of secretion and sudden arrest of function seem to be the most important.

Joining these facts together we find that cancer characters tend to appear in epithelial tissues which are nearing, or which have reached, the hereditarily fixed limits of functional capacity—that is to say, among cells which exhibit diminished capacity for cytoplasmic function and increased capacity for nuclear division of an abnormal kind. We use the word *among*, and not in, advisedly, because there is no reason to suppose that the worn-out, senile, epithelial cells themselves become cancer cells. We must rather suppose that these worn-out cells, which are ill adapted to the changes in the environment associated with the origin of cancer, perish, and are removed, and that their place is taken by younger undifferentiated cells, and that among these younger cells some possess capacities of vegetative growth which are of great value in enabling them to survive under the altered conditions, and during the struggle for room and nourishment going on with neighbouring cells. Of these abnormal characters, diminished capacity for cytoplasmic function and increased capacity for nuclear division seem to go hand in hand. As cytoplasmic function decreases assimilation increases, and as the nucleus ceases to direct cytoplasmic activity along functional lines, it tends to be exercised in initiating rapid and disorderly cell division.

Having thus indicated some of the main features which distinguish the cancer cell from the normal epithelial cell, having associated the different bodily conditions and the external influences found during the origin of cancer with one common factor, disturbance of nutrition, we are now in a position to ask whether the conditions, under which these new cancer characters appear in cells, suggest a "variational and selectional" or a "use acquirement" origin in the case of epithelial cancer.

We wish to ascertain, in other words, whether the older epithelial cells which have been exposed to the disturbed nutrition, to the mechanical or chemical irritation, to the abnormal activities of other cells, or to abnormal influences, reaching them from the body as a whole, or to the influences, whatever they may be, which predispose to cancer, we wish to ascertain whether these cells themselves become cancer cells, or whether during the struggle for existence, room, and nourishment, the increased cell proliferation, and the destruction of cells of less vegetative capacity, variations occur among the younger generations of epithelial cells exposed to the environmental change, some of which, being more adapted to live and multiply under the new conditions, survive as cancer cells.

If we analyse the changes which occur in epithelial tissues during the so-called pre-cancerous stage, we find new characters in some only and not in all the epithelial cells exposed to the changed conditions. Cancer seems, in some cases at least, to originate in a very small cell group, or even in a single cell, as we should expect if it originates in variation and not in use acquirement. In the second place, cancer is associated with the death and removal of large numbers of epithelial cells. Destruction of epithelial cells is constantly associated with all kinds of chronic irritation of epithelial tissues—in X ray dermatitis, in ulceration of epithelial surfaces due to microbic infection, in leucoplakia of the labial, buccal, and lingual mucous membrane, induced by alcohol, tobacco, syphilis, and the clay pipe, in the erosion of the os uteri the result of septic uterine discharges, in the involutionary changes which accompany chronic inflammation of glandular organs, such, for instance, as chronic mastitis. All these changes, which make up what we know as the pre-cancerous stage, are associated with the atrophy, death, and removal of large numbers of epithelial cells.

These facts strongly suggest that the cancer character originates in the younger actively proliferating cell layer rather than in the older more highly differentiated layer of epithelial cells which constantly perish and are removed. They suggest also that the cancer character arises among these younger epithelial cells as a variation rather than as an acquirement. In this sense the cancer response is the "indirect" rather than the "direct" result of some environmental change.

Such, then, in brief outline, is our conception of the cancer process as it originates in epithelial tissues.

Cancer of the Connective-tissue Type.

We now come to the consideration of the connective-tissue or mesoblastic cell, and the blastomata which arise in connexion with it. In the first place, the mesoblastic cell only responds to two environmental factors, the nutrient medium, the blood- or lymph-stream on the one hand, and the activities of other cells, epithelial or mesoblastic, on the other.

I. *External World Factor.*

Unlike epithelial cells, the connective-tissue cell has no relationship with the outside world; consequently, it does not, as a rule, show any differentiation of cytoplasmic substance into free and attached, or assimilating and secreting surfaces. The whole cell surface is bathed by the nutrient medium. It does not elaborate any external secretion because it has no free surface from which it can discharge mucus or enzymes on to the exterior of the body.

Even when it elaborates and deposits formed and inert material, such deposition occurs for the most part symmetrically, unless the irregular incidence of the stimuli interferes and brings about a corresponding inequality of deposition. This occurs in response to the unequal environmental influences of contact, pressure, and strain, as well as chemical stimuli. Even in such circumstances, the unequal stimulus which causes the unequal response is the outcome of the activities of an internal, cellular, and not an external outside world environment.

It is true that the endothelial and mesothelial cells line tubes and cavities which contain blood and lymph, but these nutritional streams exert upon the cells the influences of a nutritional and not an outside world influence, subject, of course, to alterations in the blood and lymph due to the addition of nutritive or chemical substances which reach it from the outside world.

II. *Neighbouring Cell Factor.*

When we come to the next environmental factor, the stimuli supplied by the activities of neighbouring and other cells, we find that the mesoblastic cell is peculiarly sensitive to such influences, especially to the activities of cells of the epithelial type.

Observations made during the experimental inoculation of cancer in mice show that such inoculation in any susceptible animal is followed by three definite phases: an early phase during which successful inoculation may still be practised on the same animal, an intermediate phase during which such inoculations regularly fail, and a terminal phase in which re-inoculation is again successful, and in which auto-inoculation and metastatic deposits occur. These alternating phases of susceptibility and resistance to the growth of the epithelial cancer cell on the part of mesoblastic cells afford clear evidence of an attempt on the part of the connective tissues to form a defensive reactionary growth which is ultimately overcome by the increasing growth and activity of the cancer cells. They suggest the evolution of a capacity of adaptive response on the part of cells of both groups, the invading cancer cells on the one hand, and the invaded mesoblastic cells on the other, of the same kind but of a more specific nature and with less successful result, as that made by the phagocytes to the microbes of disease.

The fact that secondary growths are less completely limited by fibrous investment than primary growths suggests either increased malignancy on the part of cancer cells which compose these metastases or of enfeebled resistance on the part of the connective tissues which surround them. In connexion with the occurrence of metastasis it is interesting to note that the quality of the resistance made by the mesoblast cells depends on specific, racial, and hereditarily transmitted characters. It is increased by age, and it can be diminished and eventually overcome by the continued

presence and growth in the tissues of a primary cancerous tumour.

Moreover, it is possible, as Bashford has shown, to raise the stroma-compelling capacity (i.e., the virulence) of epithelial cancer cells towards the resistance-offering capacity of the connecting tissues in any race of mice by passing the grafts through a series of inoculation generations in a number of individuals of the same race. This shows that it is possible to raise the malignancy of epithelial cancer cells by cultural methods, in the same way that the virulence of any disease organism can be raised, the difference being that in the case of cancer the change effected is a specific and not a general one, as in the case of disease organisms. This fact, again, supports the variational and selectional origin of cancer cells.

The labours of Ehrlich and Bashford have further shown that under certain circumstances of repeated inoculation the mesoblastic cells respond to the foreign epithelial cancer cell by the growth of a cellular tissue of low grade development indistinguishable histologically from sarcoma—that is, from cancer of the connective tissue type. This occurrence (if the interpretation placed upon it by the above observers is a correct one) supplies evidence of the origin of cancer in mesoblastic cells as the direct result of an alteration in the activities of certain epithelial cancer cells which for the time being form the cellular environment of the mesoblastic cells. There is no record of the occurrence, at any rate in the human subject, of the reverse condition. That is to say, no one has seen the occurrence of cancer characters in the epithelial cells of any organ as the result of the growth of secondary sarcomatous deposits in such an organ.

Finally, we must remember the specific nature of the cancer response. The fact that cancer cannot be transferred by inoculation from an animal of one species to an animal of a different species, and that inoculation is frequently unsuccessful when practised on an animal of a different variety, affords strong evidence of the delicacy of the balance of tissue relationship between epithelial and connective tissue cells. For the viability of the cancer graft the little aggregate of abnormal epithelial cells depends on the attitude taken up by the mesoblastic cells of the host in regard to the graft. If these react moderately and in a specific manner and form a nutrient stroma the graft lives and grows; if they react aggressively and form a fibrous tissue the graft dies.

All these facts illustrate the peculiar sensitiveness of the mesoblastic cells to the cellular element in their environment, and the alterations which take place in this sensibility are of an adaptive kind. But the conditions of the "sarcoma response" differ from those of the "cancer response" in yet another way in regard to the cellular element in the environment.

Age Incidence.

The age incidence of the disease is different in the two cases. While epithelial cancer tends to originate in epithelial tissues that are becoming senile, it tends to thrive best in connective tissues that are young. On the contrary, connective-tissue cancer tends to originate in the connective tissues of young individuals. Sarcoma has long been regarded as a disease of infancy, childhood, and young adult age. Roger Williams has collected many observations which confirm the accuracy of this clinical inference and which also, on careful inquiry, suggest further important differences between epithelial and connective-tissue cancer from our present adaptational point of view.

If we take benign tumours of the connective-tissue-cell type we find that chondromata are frequently multiple, often bilateral, and sometimes symmetrical. The fibromata are frequently multiple, often bilateral, and, in the case of the multiple fibromata of nerves, are probably congenital in origin. Moreover, these tumours have been noticed in a considerable proportion of cases to take on a sarcomatous type of growth. Osseous tumours are notably bilateral and often symmetrical, and what is most important hereditary transmission can be demonstrated in some cases. Thus, Reclus reports the case of a man with epiphysial exostoses, whose sister and three sons also showed the same peculiarity, the sister's daughter was also affected, also her four children, and seven of the grand-children.

Non-malignant ovarian tumours of the dermoid and papillary and cystic forms are all frequently bilateral. When we consider malignant tumours of the connective-tissue-cell type we find evidence that sarcomata tend to be bilateral in a greater proportion of cases than epithelial cancer in the same organ. Thus Gross reports 1664 cases of mammary cancer in which only two were bilateral, while in 156 cases of mammary sarcoma three were bilateral. In the ovary malignant tumours are frequently bilateral, but even here ovarian sarcomata, especially the round-celled variety, tend to be bilateral in a greater degree than other malignant growths. They occur chiefly in early life. In the testes round-celled sarcoma again is the usual and more frequent form of bilateral tumour. On the other hand, teratoid and dermoid non-malignant testicular formations do not seem to be bilateral.

Of the early life renal tumours, bilateral sarcomata are the most frequent. Glioma of the retina is frequently congenital and usually double-sided, and curiously and most important as in the case of epiphysial exostoses it is often hereditary. Newton records a family of 16 persons, of whom 10 died from glioma of the retina. The pigmented choroidal sarcomata are occasionally bilateral. Myeloid sarcoma of the lower jaw is sometimes bilateral.

Putting these facts together we find that tumours of connective-tissue type are often bilateral, and sometimes symmetrical in arrangement; they are sometimes congenital and usually occur in childhood or early adult life, and they are occasionally familial or hereditary. Now bilaterality and congenital origin suggest developmental and general, rather than environmental and local influences as factors in causation; while hereditary transmission, especially in the ocular glioma cases, also points in the same direction. Just as, on the other hand, the absence of bilateral arrangement and early life origin in the case of epithelial cancer suggest a diminished influence on the part of such factors, though developmental tendencies may presumably operate even here as predisposing causes, in so far as they exert an influence on the epithelial tissues to yield to or to resist the senile change.

In the same way mechanical and chemical irritation by external agencies, which play so important a part in the causation of epithelial cancer, must be of secondary importance in the case of cancer among cells which have no external world factor in their environment. But if, on the other hand, we recall the peculiar sensitiveness of the mesoblastic cell to the life activities, physical and chemical, of the neighbouring cells we are on firmer ground. This sensitiveness to "other cell" activity seems peculiar to mesoblastic cells of certain connective-tissue types, just as sensitiveness to the secretions of micro-organisms is peculiar to the phagocyte, another specialised type of mesoblast cell. It is, indeed, possible that the supposed association between traumatism and sarcoma may really depend on a reaction on the part of the connective-tissue cells to the abnormal activities of the extravasated red and white blood cells at the site of the injury rather than on the injury done to the connective-tissue cells themselves.

Nutrient Medium.

We must not omit to consider the powerful influence exerted by the nutrient medium, the remaining factor in the mesoblastic cell environment.

Looked at biologically, this nutritional factor resolves itself into a cytological one. It becomes a question of changes in the cellular elements in the blood and lymph streams, and of changes in the secretions or excretions poured by the body cells of various types into these two streams of nutrient material. The difference in chemiotactic capacity between cancer and sarcoma cells is of much interest from this point of view, and cannot, I think, be wholly explained by a difference of primary location in the two kinds of cancer cells in regard to the lymphatic and blood channels. The epithelial cancer cell perishes in the blood stream and flourishes in the lymph stream, while the connective-tissue cancer cell flourishes in the blood stream more luxuriously than it does in the lymph stream, and this difference in relationship would seem to depend partly on a difference in sensitiveness to the activities of the endothelial cells which line the lymphatics and the capillaries respectively.

Finally, the fact that increased vegetative growth and decreased functional activity, the two fundamental characteristics of malignancy, are present in both types of cancer,

not only confirms the suggestion that the cancer process is an adaptive response in both cases, but it also suggests that the particular environmental phase to which the cells are reacting, and to which, so to speak, they are trying to become adapted, has this feature in common in the two types—namely, that it is an environment which favours vegetative activity and does not favour functional activity. While the further facts—namely, the slender association of mesoblastic cells with an external environmental factor, the slight influence of external stimuli in the causation of connective-tissue cancer, the occurrence of bilaterality, and congenital origin, and occasional hereditary influence in sarcomatous tumours—all these suggest the importance of developmental factors and nutritional influence as opposed to external stimuli in this disease.

Moreover, the absence of any keen struggle for cellular existence and of active cellular proliferation, or of extensive cellular destruction, during the pre-cancerous stages of connective-tissue cancer suggests that the conditions under which sarcoma originates are not identical with those under which cancer of epithelial type originates. And in view of the special sensitiveness of mesoblastic cells to the activities of other cells it is possible that it is in this direction that the explanation of the differences in the origin of cancer in the two cases is to be sought.

Benign Tumours.

We must now consider the blastomata which arise among cells of epithelial and mesoblastic type, and which are not characterised by malignant features.

Looked at from the standpoint of adaptational response the difference between benign and malignant tumour formation becomes a question of degree. It depends on a difference in capacity on the part of the cells which compose the tumour to live and multiply in an abnormal environment of a special kind. For instance, the cells of the epithelial adenoma of malignant type are able to live and multiply in an environment formed by cells of quite another type, exercising activities of another kind, such, for instance, as that provided by the mesoblastic cells of the lymph gland. The cells of the epithelial adenoma of the benign type, on the other hand, have not got this capacity, they can only live and multiply, and that to a limited extent, among cells and tissues of the type to which they themselves belong.

It is true that the cell character and potentiality have been so far modified as to enable these cells to grow in a more or less orderly fashion in an environment in which the external world influence has been reduced to a minimum, and that as a consequence such cells have lost much of their capacity for normal function and normal secretion. But in spite of this partial change they are quite incapable under the ordinary conditions of benignity of living and dividing in the environment provided by a lymph gland, a situation in which cancer cells can flourish.

In the same way the cells of the benign tumour of the connective-tissue type, the chondroma, the osteoma, and the fibroma, resemble the cells of the benign epithelial tumour. Under normal conditions of benign growth and homotropism they can only flourish when growing in a community formed by cells of their own type of tissue.

It is true also in the case of these benign blastomata of hylic type that the new characters acquired by the cells which compose them enable them to grow and divide in a more or less orderly fashion in an environment which is not normal, and in which the relationship which normally exists between mesoblastic tissues of different sub-types has been modified by locally acting causes such as traumatism, or more general factors such as developmental potentialities and possibly abnormal internal secretions. But they do not while remaining benignant vary beyond this point. The cells composing a fibroma or osteoma of benign type cannot live and multiply in the environment provided by the lymph gland tissue, while the cells of the malignant fibroma or osteoma can live and grow in such unusual surroundings.

Teratomata.

So also with the teratomata. The cells which give rise to a teratoma are cells possessed of certain characters analogous to those of germ cells, from which probably in some aberrant form they are directly derived. They are cells which have inherited or acquired a capacity to live and multiply and exhibit teratoid characters in surroundings and under conditions unusual in germ cell development.

We are ignorant of the causes which start such aberrant or displaced cells on a course of abnormal cell division and tumour formation, but we are probably right in regarding the whole process as a response (restricted within the limits of hereditary potentiality) on the part of such cells to the abnormal environment in which they are placed. Moreover, these teratomata, which are really blastomata arising among toti-potential cells, exhibit the same transitional characters and the same tendency to diverge into malignant and benign types as the blastomata which arise in multi- or uni-potential cells—that is, in cells of epithelial or connective-tissue type.

Chorion-epithelioma is especially interesting from this point of view. Here is a blastoma arising among uni-potential cells, of extraneous and fœtal, or rather trophoblastic, origin, which have acquired a capacity to live and multiply in situations and under conditions foreign to their normal habitat. They are no longer sensitive to the restrictions to growth of a homotropic kind imposed on such cells by the internal secretions, associated with the metabolism of the lutein ovarian tissue, or the fœtal tissues, while they have at the same time acquired increased vegetative capacity. In the one form of activity they form the benign hydatid mole, in another more active form they give rise to the extremely malignant chorion-epithelioma, and the point of interest is that between these two extremes they exhibit transitional characters, intermediate varieties, half-way steps, as it were, on the way to the more completely adapted form shown by the malignant type.

Thus, while the structural and functional differences which separate the extreme types of benign and malignant blastomata represent different degrees of adaptive capacity, on the part of the cells which compose them, to environmental change of a slight or profound character, there are tumours of an intermediate class in which the cells show transitional characters, and in which it is difficult to decide whether they should be included in the benign or the malignant group.

Surgeons are familiar with tumours which originate as benign growths, and which for many years continue to exhibit such features, but which, under the influence of certain imperfectly understood environmental stimuli, of which imperfect removal seems to be one of the most important, begin to vary away from the benign type and to exhibit a capacity for vegetative and peripheral as opposed to central growth, and which under certain conditions may vary further still, and, losing their homotropic tendencies, may originate metastatic growths. Many observers have noted that among benign tumours the chondromata are especially liable to give rise to such secondary growths; this peculiar tendency may well be associated with the peripheral mode of growth characteristic of such tumours. Kirche and others have described multiple metastases in primary fibromyoma of the uterus of originally benign type.

Benign tumours of epithelial type also give rise to secondary deposits under special conditions thus: Adami, Finley, and Russell have shown that the secondary growths derived from benign adenomata of the liver sometimes display malignant characters. There is, indeed, every reason to suppose that cells can and do escape from benign tumours just as they do from placental chorionic tissue in normal pregnancy, or just as they do constantly in the case of malignant growths, and the question of their subsequent growth and proliferation in the new situations would seem to depend on a difference in capacity between benign and malignant cells to overcome the resistance offered by the invaded tissues.

But not only do the cells of benign tumours under certain conditions exhibit this capacity to originate detached growth foci, the apparently normal cells of an organ like the liver or the thyroid may, under certain circumstances, exhibit the same tendency. The attempts at cell regeneration which accompany the process of biliary cirrhosis seem to provide the conditions favourable for the origin and growth of new liver cells capable of functioning as normal liver cells or under other conditions of forming benign adenomata, or, again, of adeno-carcinomatous tumours capable of originating metastases in other tissues.

This development of liver cells of transitional types during cirrhosis, a process characterised by cell destruction, cell proliferation, and nutritional impairment, is of especial interest in connexion with our present conception of cancer as an adaptive response, depending on variation and selection

among cells exposed to environmental change. It also serves as a connecting link between blastomatosis on the one hand and cell metaplasia and blastomatoid hypertrophy, and with regeneration of tissues and organs, and the process of repair which accompanies the healing of wounds on the other.

All such processes thus fall into line as examples of adaptive response on the part of cells of different types to different conditions. The same is true of thyroid tumours. Adenomatous growths, structurally benign, of thyroid origin have been found in the cancellous tissue of bones in various situations, displaying all the destructive and vegetative activities characteristic of malignant tumours. On the contrary, thyroid growths, undoubtedly malignant, frequently elaborate colloidal material in newly formed acini, the cells of which, though of malignant type, have retained some of the functional capacity of normal thyroid cells. Moreover, in other situations typically malignant primary tumours of considerable age and size have been encountered unaccompanied with any evidence of secondary deposit. Moreover, the malignant tumours themselves afford examples of every degree of malignity, from the slowly growing atrophic to the rapidly growing, widely disseminating virulent type.

The peculiar tendency of thyroid cells to grow in bone is another example of the delicate, and in some cases specific, nature of that relationship between tissue cells of different types of which we have already spoken, and we can only suppose that cells are under certain circumstances carried from thyroid and liver benign tumours, as they are under other circumstances carried from other organs and other tissues, such as chorionic villi, and come to rest in many situations, but only those cells survive and multiply which find themselves in tissues and in situations which provide an environment favourable for their growth.

Thus we are led to regard benign and malignant tumour formation as a process of adaptation on the part of certain cells to environmental factors which concern their welfare as cells rather than the welfare of the organism as a whole.

Cancer Character.

The change of character which distinguishes the cancer cell from the normal cell is of a retrogressive rather than a progressive kind, or rather largely retrogressive and partly progressive. It is a change comparable with that by which a parasite becomes adapted to an environment which affords diminished scope for functional activity, and increased facility for the assimilation of nourishment.

In the epithelial cancer cell, increased vegetative activity is obtained at the expense of diminished power of secretion and reaction to external stimuli. In the connective-tissue cancer cell vegetative activity is obtained at the expense of structural differentiation of the cytoplasmic substance. Thus in cancer there is a disturbance of the normal relationship between nuclear capacity for directing cytoplasmic metabolism along functional lines, and nuclear capacity for initiating cell division.

In proportion as the cytoplasm ceases to be sensitive to use stimuli and becomes increasingly sensitive to nutritional stimuli, in such proportion the nucleus ceases to direct cytoplasmic activity along functional lines useful to the organism, and directs it along lines of assimilation useful to the cell. In proportion as the cytoplasm ceases to respond to the activities of neighbouring cells, nuclear division escapes from the restrictions to too frequent cell division normally imposed on healthy cells by the activity of neighbouring cells of different type. Moreover,[3] all these increased capacities in one direction and diminished capacities in other directions which go to make up the cancer habit are qualities possessed in somewhat less degree by normal cells. Some facts noted by Ehrlich seem also to suggest that under certain circumstances the cells of a repeatedly inoculated mouse cancer may partly revert to the condition of normal cells.

All these facts strongly support the conclusion that the complex cell change that we associate with cancer has been built up by variational changes from the normal type, and that one of the stages passed through is represented by the various forms of benign growth. They suggest that the external cause of epithelial cancer is to be sought in some change in one of the three factors which make up the environment of the epithelial cell, in interaction with an internal factor, the potentiality, hereditary or acquired, of the cell exposed to the change. Whereas in cancer of the connective-tissue type, cell potentiality as affected by developmental and hereditary influences seems of more importance than environmental change.

The cancer response differs from the response made by germ cells to environmental influences in this respect. The germ cell and the cancer cell have both ceased to respond to "use," and only respond to "nutritional" stimuli; but in the cancer cell, unlike the germ cell, the change is brought about by retrogressive variation to a parasitic habit, with the loss of a capacity to undergo normal development which is retained by the germ cell.

Summary.

Thus we are led to describe blastomatosis as an adaptive response on the part of individual cells, or cell groups, to environmental change of three kinds: alteration in the stimuli which reach the cell from the outside world; alteration in nutrition; alteration in the activities of the other cells which compose the organism. This adaptive response may be "indirect," the result of variation among the cells exposed to the changed conditions accompanied by selection of an *inter*-cellular kind, or it may be "direct," and the result of a process of variation in the physiologically differentiated parts which compose the individual cell, accompanied by selection of an *intra*-cellular kind, in which case it represents a "use acquirement."

The new cell characters which so arise may be grouped in two main divisions—one characterised by typical growth including all the histological varieties of benign neoplasms from teratoma to neuroma, the other characterised by atypical growth including the malignant types. But between these two groups there are numerous tumours composed of cells presenting transitional characters. Yet, again, the second group, characterised by atypical growth, may be divided into neoplasms composed of cells of epithelial type, and neoplasms composed of cells of connective-tissue type. And between these two groups there are again connecting links, for the malignant tumours which arise from cells of primary mesoblastic and secondary epithelial origin tend to exhibit transitional characters.

Of the two factors concerned in the origin of malignant growth (cell potentiality and environmental influence) environmental influence plays a large part in the genesis of cancer, cell potentiality in the genesis of sarcoma. Of the environmental factors concerned, outside stimuli exert a much larger influence in the genesis of epithelial than of connective-tissue cancer.

Other Theories of Cancer.

In conclusion, we must now compare the account of blastomatosis here propounded with previous descriptions of tumour formation put forward by other observers.

Cohnheim and Ribbert.—"Pre-" and "post-" natal cell displacement, either alone or in association with diminished growth resistance, have been put forward by Cohnheim and Ribbert as causes of tumour formation.

Parasitic.—For some time the theory of parasitic infection held the field.

Von Hansemann.—This author suggested "anaplasia," the formation of new races of cells possessed of abnormal characters, in association with an abnormal distribution of nuclear cell material, as a cause of cancer.

Adami.—Stress has been laid by Adami and others on "habit of cell growth" and on the process of cell undifferentiation as it is present in metaplasia and normal cell division.

Oertel.—Assuming two kinds of nuclear material, one controlling function, the other vegetative activity, Oertel associates the loss of functional activity characteristic of cancer cells with the loss of the former kind of nuclear material during the irregular cell mitoses which accompany malignant growth.

Marchand.—Attention has been drawn by Marchand to the marked difference in potentiality between the normal embryonic cell and the embryonic cell of neoplasmic growth, which must be taken into account in any attempt to explain blastomatosis as a return on the part of certain body cells to embryonic characters.

Hauser.—From a minute examination of the changes shown by the epithelial cells of intestinal new growths Hauser put forward in 1890 the suggestion that the cells of new growths are the descendants of some single cell which, during the course of ontogenetic development, has "mutated"

[3] Gould, Bradshaw Lecture, THE LANCET, Dec. 10th, 1910, p. 1665.

or varied away from the normal character, and has given rise to cell descendants in which these new characters persist, and among which vegetative activity is one of the most important. He also associated this mutational change with excess of cell nutrition.

Adami.—Dissatisfied with any attempt to explain the origin of the new characters found in neoplastic cells by chance variation or mutation, Adami would regard such mutational change as a direct response on the part of such cells to environmental influences. Believing, further, that no one environmental stimulus is responsible for the whole cell change, Adami considers that a number of different influences may combine to cause the cancer change. Among these he enumerates the influence of cell displacement, chronic inflammation, irritation, mechanical or microbic in origin, cell senescence, impaired cell nutrition leading to cell proliferation, in association with preceding changes in the underlying connective tissues in the case of some epithelial cancers, while among subsidiary influences he mentions diminished external growth resistance and altered cell secretion.

H. Ross.—More recently H. Ross, impressed by the powerful influence exercised by the products of cell death in association with certain chemical substances of an alkaloidal nature, in initiating cell division in leucocytes and lymphocytes and some other cells, has suggested that the rapidly recurring division of cancer cells may be associated with a like cause.

Such are some of the many and various theories which have been put forward at different times to explain the origin of tumour formation, and incidentally the origin of cancer.

The present contribution makes no attempt to put forward any new explanation of the cause of cancer. It must rather be regarded as an attempt to consider the cancer problem from a wider biological standpoint by directing attention to the adaptational nature of the new characters acquired by cancer cells, and as an attempt to analyse some of the conditions under which benign and malignant tumour formation takes place.

The result of such an analysis goes to show that cancer, like all "new growth," must be regarded in the light of a response of an adaptive kind on the part of certain cells or cell-groups of varying potentiality, to changes in their environment. It suggests that in epithelial cancer, at any rate, this response takes place under the same conditions as those which are associated with the occurence of variation and selection among other organisms when exposed to environmental change and where evolution of new characters is taking place, especially in response to changes in the external environment. And the suggestion is therefore made that blastomatosis, including cancer and certain other forms of cell multiplication, takes place under the influence of the same evolutionary factors—namely, variation and selection of the "inter-" or "intra-" cellular kind.

The old inquiry still remains. It is the ascertainment of the kind of environmental influence on the one hand, and the special factor, hereditary or acquired, in cell potentiality on the other, which are independently or conjointly responsible for initiating the process whereby the new characters arise "innately" in, or are "acquired" by, cells engaged in neoplasmic growth.

Leicester.

DIFFUSED CANCER OF THE FEMALE MAMMARY AND THORACIC INTEGUMENT ("CANCER EN CUIRASSE").

BY SIR GEORGE THOS. BEATSON, K.C.B., M.D. EDIN.,
SURGEON TO THE GLASGOW WESTERN INFIRMARY AND TO THE GLASGOW CANCER HOSPITAL.

THE clinical experience of most surgeons is that primary carcinoma of the mammary integument is not of frequent occurrence, and that the most usual site of it when it does occur is the region of the nipple and its areola. Its occurrence in this latter situation is what might be expected, seeing the rôle irritation plays in the development of malignant disease, for the nipple and the skin around it is often the seat of cracks and fissures that are not always easy to heal and that are sometimes submitted to somewhat drastic measures of treatment. Should primary cancer of the nipple show itself it may be in the form of a squamous-celled epithelioma, or of a glandular carcinoma, originating in the epithelium (1) of the sebaceous glands or (2) of the galactophorous ducts. It is in connexion with cancerous changes in the duct epithelium that Paget's disease is a recognised factor. Commencing as an eczematous condition of the nipple and areola of a purely inflammatory nature, it in time brings about in the epithelium of the ducts alterations which spread to the deeper parts of the breast, with the result that we have the acini becoming distended with proliferating epithelium and true carcinoma mammæ is developed.

There is, however, another form of cancer of the mammary integument which is seen from time to time and is characterised by a dense unyielding leather-like state of the skin of the thorax. Although referred to by Howard of the Middlesex Hospital in 1792, attention to this class of case was specially drawn by Velpeau in 1838, who described it under the name of "ligneous cancer" in plates, or *diffused* over the mammary integument, and he termed it "cancer en cuirasse." He stated that he had often met with it, and he emphasised as its characteristic the brawny (*ligneuse*) change present in the skin. He regarded the cases as illustrative of the wide area that a carcinoma may involve by continuous spread from a central focus. Some cases have been published that have been regarded as primary examples of this condition, but they are very few in number and are by no means conclusive. As a rule, the affection is secondary, and either accompanies carcinoma of the mamma or makes its appearance after the removal of a breast for malignant disease. At the Glasgow Cancer Hospital I have met with four such cases, the first one, shown in Fig. 1, being admitted on March 25th, 1895. It was of a secondary nature and was of three months' duration, having shown itself nine months after the removal of the left breast for a cancerous growth. The illustration (Fig. 1)

FIG. 1.

Typical "cancer en cuirasse."

shows the extensive involvement of the mammary integument on the left side and its extension to the right breast, which was tense and tender and was entirely occupied by a firm round swelling, reddish all over the surface, with some œdema in the surrounding tissues. Part of the cancerous area on the left side of the thorax had ulcerated, and there was present that marked œdema of the upper extremity which is such a constant and important feature of this affection. There was also present some fluid in the left pleura. The progress of the case was rapid. The notes say that the

patient became more oppressed in breathing and more cyanosed, dying on May 6th, about six weeks after admission.

As already stated, Velpeau regarded these cases as ones of *cancer of the mammary integument*, and as illustrative of the wide area that a carcinoma may involve by continuous spread from a central focus, and this has been the generally accepted view of them ever since. Of late years this view has been called in question by Handley, who states on page 147 of his work on "Cancer of the Breast and its Operative Treatment" that the prevalent idea that "cancer en cuirasse" is due to the spread of the disease along the deep cutaneous plexus of lymphatics is a belief which appears to be quite erroneous, and on page 149 he gives his view of the condition as follows:—

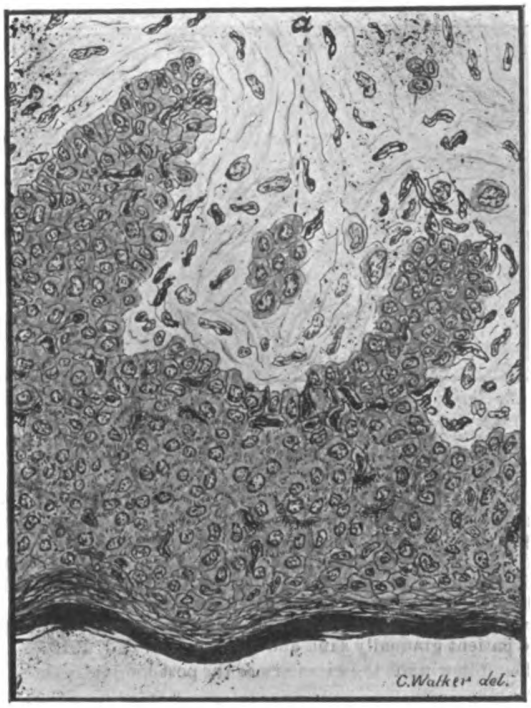
> The fact is that "cancer en cuirasse," so far as it concerns the skin, is in its earlier stages essentially a non-cancerous condition, identical with the pachydermia which is seen in elephantiasis arabum, and in some cases of long-standing eczema, dependent on the same cause, obstruction to the return of lymph from the skin. Later on it is usually complicated by nodular invasion of the skin. The swelling of the arm in breast cancer on the affected side with brawny thickening of the integuments, is a less marked example of a very similar condition. Here it has never been suggested that the skin of the arm is infiltrated by cancer.

In view of this divided opinion I think the following case is of interest and importance, as it throws some light on the exact nature of this condition termed "cancer en cuirasse."

The patient, a single woman, aged 63 years, was admitted to the Glasgow Cancer Hospital on Oct. 21st, 1910, suffering from inoperable carcinoma of the right mamma. The history she gave was that she was a shawl-twiner by occupation and had always enjoyed good health until her present illness, which began about three years previously with pain and uneasiness in the right breast. She had recently got much worse. She did not consult a medical man until July, 1910, when she was advised to obtain hospital advice and treatment. This she did, and was admitted to an infirmary. Her case was not considered suitable for operation and she underwent a course of X ray treatment without benefit. The hospital report states that on her admission on August 1st, 1910, there was a hard swelling in the right breast about the size of a cocoa-nut, moveable over the underlying tissues, but fixed in the breast substance. The skin over it was adherent and the nipple retracted, but no glandular masses were felt in the axilla. The lungs were normal. On August 4th applications of the X rays were begun and continued daily. On Sept. 4th it was noted that the skin had become affected and on the 18th that it was extensively involved, the breast tumour, however, being smaller. Later, swelling under the right arm showed itself, and the arm and hand became swollen. On Oct. 8th the patient went home.

The patient's condition when she came to the Glasgow Cancer Hospital was a very distressing one. The right arm was swollen and brawny except on the dorsum of the hand, where the swelling was puffy and softer. The right breast and the right axilla were the seat of superficial ulceration, and the right nipple was replaced by a sloughing mass. The skin of the front of the thorax on each side was dense, unyielding, and leathery, and both mammæ, especially the right one, were hard and firm and fixed to the chest wall. Perhaps, however, the most striking feature in the case was the red erythematous tint of the skin of the anterior thoracic wall, of the right shoulder as far up as the root of the neck, and of the front of the right arm down to the elbow. In some parts, as over the sternal and right clavicular region, this redness was replaced by a livid and almost ecchymosed condition of the skin. All over the erythematous region, and especially on the anterior aspect of the thorax, were numerous vesicles and bullæ containing fluid of a purplish colour. On the surface of the right mamma the bullæ had burst and the mammary integument was in places covered by a soft, yellowish sero-purulent discharge. Above the left mamma some nodules were to be felt extending in the direction of the left shoulder, but there was an absence of nodularity in the affected skin of the right side, and generally it was smooth in character. On the right side of the chest the disease was sharply defined in front by the costal margin, and on the left side it did not reach so low, being limited by a line drawn from the ensiform cartilage along the base of the left mamma to the anterior border of the axilla. The patient complained of a constricted feeling around the chest, and she had great difficulty in moving herself in bed. After admission the section of a bit of skin taken from the extending edge of the redness and examined in the research department of the hospital showed the cells of the deeper layers of the rete Malpighii burrowing amongst the subcutis almost as in the growing edge of an advancing epithelioma, while here and there several separated groups of cancer cells were seen scattered in the subcutis suggesting invasion of the lymphatics of the skin and the involvement of the cutis in the cancerous process. This state of matters is shown in Fig. 2.

FIG. 2.



Section of skin from extending edge of redness, showing, *a*, a separated group of cancer cells in the subcutis.

FIG. 3.

Shows the deeper layers of the subcutis with cells of a spheroidal type, and they exhibit a marked alveolar arrangement with abundant fibrous stroma and present the typical aspect of a scirrhus cancer.

The after-progress of the case was marked by considerable extension of the redness and induration of the skin both on the right and left sides of the chest, and subsequently it extended from the right shoulder to the scapular region as far down as the level of the tenth dorsal vertebra. Several large areas of ulceration formed on the chest walls in the erythematous part of the skin, and here and there were present brownish crusts, which revealed reddened and

FIG. 4.

Section of the skin through the margin of one of the bullæ, showing that while the surface layer of horny epithelium remained, being somewhat thickened, the rest of the integumentary elements were replaced by cancerous cells, among which was a certain amount of connective tissue.

oozing surfaces when removed. With the increasing density of the skin the feeling of constriction of the thorax increased and the patient could not move unassisted. Under the pain and discomfort the general health suffered and sleep could only be obtained by opiates. There was slight fever with a dry and tremulous tongue and quiet muttering delirium. The patient gradually sank and died on Dec. 2nd, 1910.

The following is the summary of the post-mortem report:—

The body was that of a well-built woman and was not emaciated. A large ulcerated area was present in both pectoral regions. The right breast was greatly involved and the ulcerating process extended to the edges of the ribs and the costal cartilages of the right side, to the right axilla, and to the scapular region behind. The right axilla showed also patches of ecchymosis. The ulceration did not involve the whole of the left pectoral region but only that portion nearest to the sternum.

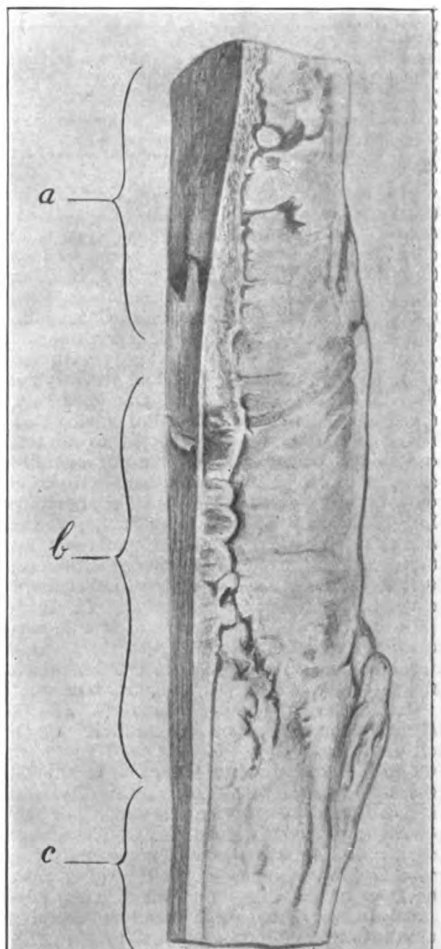
In the thorax the heart was found to be slightly hypertrophied, and there was thickening of the pericardium. Near the apex of that organ were several "soldier's" spots. The heart wall was slightly fatty, and several small atheromatous patches were present in the aorta. The right lung was very adherent to the costal pleura and the pulmonary pleura was distinctly thickened near the apical region. The left lung was only slightly adherent to the costal pleura. There was some hypostatic congestion of the lungs, but no carcinomatous nodules were present on the surface or in the substance of the lungs. There was no cancerous injection at the root of the lungs. Beneath the right breast the fatty tissue was pigmented and of a deep yellow tinge, and on the right side the skin, subcutaneous and muscular tissues were adherent to the ribs and sternum beneath. The right parietal pleura was studded with areas of cancerous infiltration, and the right lung, as already stated, was markedly adherent to the chest wall and was separated with difficulty. The right pectoral muscle was infiltrated with the growth and the interfascial septa were markedly developed and showed distinct cancerous infiltration.

In the abdomen the liver was congested and slightly enlarged and there was some fatty infiltration. No cancer nodules were to be seen anywhere on its surface or in its substance. The kidneys were congested and showed a condition of sub-acute nephritis. The suprarenals were smaller than usual, but were otherwise healthy. There was some congestion of the spleen, but it was otherwise quite normal and showed no carcinomatous nodules on its surface, or in its substance. The uterus was bicornuate and the ovaries atrophied.

From the point of the chest on the right side a long strip of skin and subcutaneous tissues was taken over the ulcerated area, but below, extending towards the abdomen into the normal skin (Fig. 5). This section, viewed from the side, shows at (*a*) the blackened necrotic and thinned skin and at (*c*) skin of normal appearance and thickness. At (*b*), between these two extremes there was an area of active cancerous growth in the cutis. A section of this area at the advancing margin of the skin lesion showed under the microscope a close permeation of the lymphatics of the cutis by single strands and small groups of cancer cells, and associated with this a well-marked thickening of the cutis. The epithelial covering of the skin in this area showed very distinct desquamation and the papillæ of the cutis were fibrosed and œdematous. There was, however, more than this skin lesion. In addition the subcutaneous tissue underlying the area displayed abundant strands of carcinoma spreading in the lymphatics and also permeating the fat. Similar examination of the dark ulcerated skin at (*a*) lying central to the advancing margin showed necrosis of the cutis and no nuclear staining of cancer cells or normal tissue cells.

With the foregoing clinical and pathological facts before us we are now in a position to consider the exact nature of this case, and if it comes under the category of "cancer en cuirasse" to express an opinion as to whether or not the condition arises from dissemination of the cancer cells through the lymphatic vessels of the cutis vera, or is simply, as Handley suggests, "a non-cancerous condition identical with the pachydermia which is seen in elephantiasis arabum, and in some cases of long-standing eczema, dependent on the same cause, obstruction to the return of lymph from the skin."

FIG. 5.



From its clinical manifestations I have no hesitation in placing the case in the category of those described by Velpeau under the group of "cancer en cuirasse." The only disturbing element entering into it, and that could be in any way appealed to as altering its ordinary course, is the treatment for about three weeks by the X rays. To this fact, however, I do not consider any special weight should be attached, as the condition of the thoracic wall on the patient's admission to the Glasgow Cancer Hospital was not that of an X ray dermatitis, and the subsequent microscopic examination of the skin supported that view. Going, then, on the assumption that the case was one of Velpeau's "cancer en cuirasse," it is necessary to study it a little in detail to clear up the exact pathological lesion present. From the patient's own account of her illness it is not very evident when the tumour in the right mamma showed itself. It may or may not have been present during the two or three years when she suffered from sensations in the breast of a vague and uneasy nature, yet not sufficient to necessitate

her seeking medical advice. The first distinct proof of the existence of the tumour is in August, 1910, when she was advised to enter hospital, for the infirmary report says that there was then found in the right breast a hard swelling of the size of a cocoanut. It is also clear from the report that at this time the skin of the thorax was not affected, as it is distinctly stated that it was Sept. 4th when it began to be involved. These facts show that the integumentary lesion was not a primary one but was associated with a pre-existing malignant tumour of the right breast. Nothing is said in the report as to any microscopic examination of the skin in September, 1910, but we know that within eight weeks of that time the section of a bit of skin taken from the extending edge of the thoracic redness revealed a cancerous condition of the integument (see Figs. 2 and 3), a state of matters not in accordance with Handley's view that cancer en cuirasse, "so far as it concerns the skin, is in its earlier stages essentially a non-cancerous condition." Were this so, the section from the extending edge of the redness should not have contained the "several separated groups of cancer cells seen scattered in the subcutis suggesting invasion of the lymphatics of the skin and the involvement of the cutis in the cancerous process." This suggested invasion of the lymphatics received full confirmation by the section of skin taken after death, which showed, as stated, "a close permeation of the lymphatics of the cutis by single strands and small groups of cancer cells, and associated with this a well-marked thickening of the cutis."

Before considering further these divergent opinions as to the exact nature of the condition present in cancerous pachydermia or so-called "cancer en cuirasse" it is necessary, in view of the part played by the lymphatic system in the dissemination of cancer, to draw attention to the distribution of (1) the cutaneous lymphatics of the thorax, and (2) of the lymphatics of the breast.

1. *The Cutaneous Lymphatics of the Thorax.*

The best grouping of these is that of Poirier and Cuneo, who divide them into three territories—viz., anterior, lateral, and posterior, an arrangement which permits of the clearer classification of the collecting trunks of the thoracic cutaneous network of lymphatics.

(*a*) *Anterior territory.*—This area extends from the median line to the neighbourhood of the anterior axillary line, *but it does not include the integuments which cover the centre portion of the mamma.* Its collecting trunks appear in the region of the middle line and run towards the axilla, some passing above and some below the breast. All of these anterior trunks terminate in the thoracic group of axillary glands and they represent the principal lymphatic channel of the anterior region of the thorax. This anterior territory, however, possesses *three accessory lymphatic channels* which must not be lost sight of, as they are of considerable importance. They are known as (1) the subclavian, (2) the contra-lateral, and (3) the internal mammary. The *subclavian* consists of some trunks which arise below the clavicle, run upwards and outwards over that bone, and end in the supra-clavicular glands. The *contra-lateral channel* owes its existence to the fact that there is a continuity between the networks of origin of the lymphatics on either side of the middle line of the chest. In addition to this there is a small percentage of cases where there is a decussation of the collecting trunks across the middle line. Lastly, the *internal mammary* channel represents two or three collecting trunks which perforate the anterior extremities of the intercostal spaces and, closely accompanying the perforating branches of the internal mammary artery, reach the retro-sternal glands. We have then in this anterior territory one principal homolateral axillary channel and three accessory ones.

(*b*) *Lateral territory.*—This area is drained by five or six collecting trunks which ascend vertically, perforate the axillary aponeurosis, and end, as do the anterior trunks, in the thoracic group of axillary glands.

(*c*) *Posterior territory.*—The drainage of this area is carried on by 10 or 12 collecting trunks, of which the lowest appear a little below the inferior border of the thorax. These, as well as the middle and upper ones, converge towards the axilla and terminate in the scapular group of axillary glands. Such is the general distribution of the cutaneous lymphatics of the thorax, but it is necessary to have a clear understanding as to their exact mode of arrangement in the skin, as upon this depends the mode of spread of cancer in that structure. The most recent view is that the lymphatics of the skin originate in the papillæ and form by intercommunication in the superficial layer of the dermis what is termed the *subpapillary plexus* (*a*). Underneath it, and lying some distance from it, upon or just over the deep fascia of the body, is the main parietal lymphatic plexus known as the *fascial plexus* (*c*), the two communicating with one another by vessels which start from the subpapillary plexus and dip down vertically to join directly the fascial plexus (*b*). (See Fig. 6.)

FIG. 6.

Diagram from Handley's Cancer of the Breast, p. 28, to show that subcutaneous nodules do not necessarily arise from the extension of growth along the skin.

This arrangement is not, however, universally accepted. According to others the connexion between the subpapillary and fascial plexuses is not quite so direct as given above. They hold that the vertical vessels do not run direct into the fascial plexus, but anastomose amongst themselves and form on the deep aspect of the skin an intermediate plexus which has been named by Arnold *the deep cutaneous plexus.* Of its existence Handley says he has never found any evidence in his work, and the consensus of opinion seems to be that in the skin we have only the subpapillary plexus, and that its communication with the deep fascial plexus is by the definite vertical tributaries.

2. *The Lymphatics of the Breast.*

There are two groups of these—viz., (*a*) those of the skin over the mamma, and (*b*) those of the mammary gland itself.

(*a*) *The mammary cutaneous lymphatics.*—These have a different arrangement at the periphery of the breast from that which exists in the region of the areola and nipple. Most of the former terminate in the collecting trunks of the homolateral axillary channel which collects the lymph from the anterior thoracic cutaneous territory and pours it into the thoracic groups of axillary glands, but a few of the lymphatics arising from the skin over the internal surface of the mamma may pass direct to the axillary glands of the opposite side. On the other hand, the central cutaneous lymphatics of the nipple and areola have quite a different course. They first form a superficial network with extremely fine meshes, arranged in several planes, from which numerous trunklets pass directly into the deeper plexus formed by larger trunks, known as the *subareolar plexus of Sappey*, and in which the majority of trunks coming from the mammary gland itself also terminate. We have thus in connexion with the mammary integument two sets of lymphatics quite distinct, although in close juxtaposition.

(*b*) *The lymphatics of the mammary gland.*—The majority of the lymphatics of the breast itself form a network about the lobules and milk-ducts and pass by means of collecting trunks into the subareolar plexus of Sappey, or, as Handley calls it, the subpapillary plexus. A few, however, of the intramammary lymphatics pass direct to the subclavian and supraclavicular glands, while others pass into the *deep fascial plexus* in the loose retromammary tissue. The mammary lymphatics that end in the subareolar plexus of Sappey pass to the axillary glands by means of two large trunks which leave the plexus one on its internal, the other on its external part. The internal trunk passes from the internal side of the gland around the lower border of the subareolar plexus, and runs along the lower border of the pectoralis major to the axilla. The external trunk leaves the external side of the gland and goes direct to the axilla. These two main trunks perforate the axillary aponeurosis and terminate in one or two of the glands placed on the inner wall of the axilla on the third digitation of the serratus magnus. In the case of the intramammary lymphatics that enter the deep fascial plexus, they also empty into the axillary glands, for this deep fascial plexus has certain catchment areas from which special trunk lymphatics spring, and those that receive the mammary lymphatics terminate in the axillary glands. In addition to this main lymphatic channel the mamma has three accessory channels known as (1) the axillary, (2) the subclavian, and (3) the internal

mammary. The first one is not very constant, but when present comes from the lower part of the gland and passes directly to the axilla. The subclavian is represented by a trunk which comes from the posterior surface of the breast, penetrates the pectoralis major, and passing between the two pectoral muscles ends in the subclavian glands. Lastly, the internal mammary comprises the lymphatics coming from the inner part of the mamma. They follow the perforating branches of the internal mammary artery and reach the retrosternal glands, just as do some of the cutaneous lymphatics.

Seeing that a mammary cancer must be regarded as co-extensive with the lymphatics that drain it, we have three groups of these vessels in connexion with the breast—viz., (1) the cutaneous, (2) the areolar, and (3) the glandular lymphatics, by any of which we may have both local and general dissemination taking place. As regards the general dissemination, it was, until recently, thought that it occurred chiefly by the blood stream, but Handley's work has made it more probable that this is not the case, and that the most frequent channel is the lymphatic system.

To understand how cancer spreads locally and generally in the body it is necessary to bear in mind the conditions that give rise to this characteristic of the disease. There are two ways in which a carcinomatous growth extends. The first one is by "*infiltration*," which is a local process and consists of a gradual pressure destruction of the healthy surrounding tissue. The other one is by the passage of cancer cells along the *lymph channels connected with the spot where the cancerous growth has commenced.* Having gained access to these channels, the cancer cells then pass to the lymphatic glands connected with these lymphatics, and in this way there is laid the beginnings of a mode of dissemination of the cancerous growth throughout the body, which gives to carcinoma its most fatal characteristic. The possibility of this spread of the disease is due to the fact that there is a continuity between the whole of the lymphatic system of the body, and thus there can take place the passage of cancer cells to distant parts of it. The plan on which this continuity is arranged has been specially studied by Handley, whose general idea of the lymphatic system is that it is a vast horizontal network of fine vessels lying on the deep fascia. Into it are poured by numerous fine vertical tributaries, first the lymph from the skin and its appendages, such as the mamma, and, secondly, on its deep aspect the lymph of the muscular and periosteal lymphatics. In this way the entire body is invested by a network of intercommunicating channels. It is not necessary to go here into further details about this general lymphatic investment and the six drainage areas into which Handley divides it. What should be remembered is that six sets of lymphatic trunks convey the lymph to the (1) cervical, (2) axillary, and (3) inguinal glands, each of these groups of glands draining different areas, and that the different areas, though distinct, are not isolated from one another, for between them are lines or zones in which it is true there are no trunk lymphatics, but there are present narrow and fine tortuous vessels in which the lymph stream is very slow and at its feeblest and through which only very fine particles can pass, and that are capable of being opened up, under certain conditions, so as to create channels of communication, just as happens in the establishment of the collateral circulation after ligature of a main artery.

To explain the passage of cancer cells between areas thus shut off to some extent from one another Handley calls in the assistance of the proliferating power of the spreading tumour cells, and considers that it is by "centrifugal lymphatic permeation" that they find their way into the fine lymphatic vessels between the areas and thus pass into adjoining areas without changing their conditions of life. I confess I have never thought this term "permeation" of cancer cells a happy one, as it does not correctly represent what takes place The word permeation implies diffusion through the tissues, just as odours permeate the air or a dye spreads itself through cloth. It suggests, in fact, passage through the pores and interstices of a substance without rupture or diplacement of parts. This is not what happens in the case of the extension of a cancerous tumour by the lymphatics. Underlying the whole process is mechanical pressure, and the term I have always used for the lymphatic spread of cancer has been "*pressure dissemination.*" The correctness of this view is apparent if we consider for a moment what happens in connexion with a cancerous growth. Cancer consists of an abnormal and unexplained growth of the cells of a part. The new cells which are formed by this irregular and inexplicable activity collect together and form a swelling or tumour as it is called. Such a local collection of cells would probably do no harm were it to be small in size and not undergo any increase, and sometimes this happens, so that a person may carry about with them for years a limited cancerous tumour and be none the worse for it. Such is not, however, the usual course of events. The cells multiply and room must be found for them, so those on the outskirts are compelled to find an outlet of escape. This they do largely by the lymph channels and it is done under pressure from the accumulating cells at the original centre of activity and at any new foci at a distance, for some of the cells forced into the lymph channels have the same proliferating power as the original ones that began the morbid process. When in the lymph channels they not only induce a small-celled infiltration which ultimately forms a new connective tissue and thus brings about a perilymphatic fibrosis, but the multiplying cells rupture the smaller lymph channels and in this way destroy the continuity of the lymph vascular system of the part affected. The spread, then, of a cancer is really a "pressure dissemination," and this is supported by the fact that relief may be obtained in another direction. Thus, the tension of the cells in the primary growth may cause ulceration in it and by this discharging surface the pent-up cells may find exit, lessening the spread along the lymph channels. In no other way can we explain certain clinical facts, such as the slowness of glandular implication in many cases of cancer of the body of the uterus. Here the disease soon sets up ulceration of the mucous membrane, and the cells finding an easy escape put no pressure on the lymph channels, so that the parametrium is not involved in these cases until a late date.

Keeping in view this principle of pressure dissemination as the determining factor in the lymphatic spread of cancer, I think it offers an explanation of what takes place in the condition of "cancer en cuirasse," and makes clear its exact pathology. What happens when a mammary carcinoma forms is this. As the activity of the disease goes on the proliferating cells have to find some means of escape. Pressed by the accumulating cells of the primary growth those at the periphery and elsewhere crowd into the lymph spaces and channels, making their way along the paths of least resistance. Various outlets are open to them, because, as already described, the lymphatics in this region are arranged in several groups—viz., the cutaneous, the subareolar plexus of Sappey, the circum-mammary, the retro-mammary, and the intra-mammary, this last being made up of the perialveolar and periductal lymphatics. All of these groups are in close touch with one another and they drain, as we saw, into the axillary glands, the supra-clavicular glands, the retro-sternal glands, the lymphatics of the opposite side, and the lymphatics of the anterior abdominal musculature. Whatever be the route first taken by the displaced cancer cells it sooner or later becomes blocked by them and also directly interrupted by their rupture of the lymph vessels. When this happens, should there be any great activity of the disease with rapid cell growth and no relief afforded by ulceration of the skin over the tumour, then other pathways are sought by the cells. So important an element in cases of mammary cancer is this question of the channels followed by the crowded-out cells that their clinical character is determined by it. Thus, if the retro-mammary lymphatics are open to the cancer cells and they follow that route, they come into touch with the deep fascial plexus which Handley has shown envelops the body, and we get widely disseminated disease which may show itself locally in the shape of multiple nodules (Fig. 7), each nodule probably marking the position of a vertical tributary between the subpapillary and deep fascial plexuses, or as distant deposits in the bones and viscera. In the same way in a case of long-standing carcinoma of the left mamma recently under my care, relief seemed given to the proliferated cancer cells mainly by the cutaneous lymphatics of the anterior abdominal musculature, nodules appearing in the skin of the abdomen as far down as the symphysis pubis, in the vulva in front, and at the anus behind, the inguinal glands being also enlarged, a condition of matters due, I consider, to the invasion under pressure of these adjacent areas by the

mammary cancer cells, all other outlets for them being closed or occupied.

In view, then, of the fact that the lymphatic spread of cancer depends on mechanical pressure exercised on the cancer cells, and that the direction in which they travel is determined by the patency or otherwise of the adjacent lymphatic passages, it is possible to offer an explanation as to what happened in this case of mammary integumentary carcinoma or cancer en cuirasse that I am recording. To begin with, everything points to the mammary tumour having existed for some time before the patient sought medical advice in July, 1910. During that time extension had probably taken place by the ordinary lymphatic channels, and it is not unfair to assume that at the time she was admitted to the infirmary the axillary, subclavian, internal mammary and retro-mammary outlets were blocked by accumulations of cells and perilymphatic fibrosis, and also interrupted by rupture of the lymphatic vessels. After admission to the hospital fresh activity in cell development evidently took place, possibly under the influence of the X rays as sometimes happens, and accommodation had to be found for these new cells. Choosing the path of less resistance they obtained it in the *subpapillary lymphatic plexus of the skin*, which was invaded by them, the tension caused by their presence setting up the red erythematous state of the skin, with its bullæ and subsequent ulceration that were such prominent features in the case when the patient entered the Glasgow Cancer Hospital. That cancer cells were present in the skin at that time the sections shown in Figs. 2 and 3 show conclusively, and as we know from the infirmary report that implication of the skin was only noticed about Sept. 4th, these sections represent a comparatively recent lesion.

Under these circumstances, I think the conclusion is allowable that we may have in cases of mammary carcinoma a cancerous invasion of the lymphatics of the skin exhibiting all the symptoms of Velpeau's "cancer en cuirasse," and that Handley's view that the ligneous hardness of the skin found in that condition is at first non-cancerous and identical with the pachydermia seen in elephantiasis arabum, and only becoming cancerous as a late event, is not tenable. Handley is no doubt right in saying that cancer infiltrates the tissues of the skin slowly and with difficulty in the vicinity of *ulcerated* primary growths, because ulceration relieves the pressure in these cases. When ulceration is not present the state of matters is different, and there comes into play forcible dissemination. Under it the cancer cells open up the lymph channels of the skin, just as the blood does the smaller arterioles in establishing the collateral circulation after ligature of a main arterial trunk, and if they happen to rupture the delicate walls of the lymphatics in the process the freed cancer cells spread very rapidly in the loose subcutaneous tissue of the skin, whether there be or be not a deep cutaneous lymphatic plexus. Taking everything into consideration, this case seems to support the older view as expressed by Erichsen and Watson Cheyne, that the condition known as "cancer en cuirasse," while occasionally arising from a fusion of numerous nodules connected with the deep fascial plexus, as might have happened with the case shown in Fig. 7, is generally the result of direct spread of the cancer cells to the lymph channels of the skin, thus emphasising the fact that in cases of mammary cancer the cutaneous lymphatics have to be reckoned with as a possible area of dissemination of the disease.

AND
L. DE C. HARSTON, F.R.C.S. EDIN., &C.

THE patient, a married woman, aged 60 years, was first seen in May, 1910, suffering from pain in the joints and muscles. She had a foul tongue, and constipation was present. Her temperature was 100° F.

Past history.—During the greater part of her life she had resided in India, but with the exception of a severe attack of dengue, there is nothing of importance to note. On her return to England some 20 years ago she seems to have entirely thrown off the effects of the fever, but suffered much from chronic dyspepsia and constipation and later on hæmorrhoids troubled her much, which were operated upon. She was strictly dieted and otherwise received appropriate treatment.

History of the present attack.—In May, 1910, she sought medical aid for pain in the joints and muscles, foul tongue, and constipation. Her temperature when first seen was

100°. The shoulders, elbows, carpal and upper vertebral and maxillary joints were chiefly affected and later the knees, and for the first four or five weeks the case looked much like one of infective arthritis. Among other things she was treated by electric light baths, but in spite of all treatment her condition rapidly became worse, emaciation increased, and there was low continuous fever; later blood and mucus were passed in the stools. She was highly tympanitic over the abdominal region. A systolic murmur at the apex which developed during the attack suggested the possibility of ulcerative endocarditis. The abdominal distension was often severe and the stools were always liquid: in fact, at this time the abdominal symptoms were far more prominent than the arthritic. Blood cultures were sterile, and the typhoid and tuberculo-opsonic reactions normal. The urine contained no albumin. Exploratory operation was suggested, but in view of the vague symptoms and absence of local physical signs it was not thought to be justified, nor was the patient in a fit state to stand an operation well.

The symptoms at this time pointed to some inflammatory infection and possibly ulceration of the bowel, chiefly in the region of the cæcum and ascending colon. There were some enlargement and tenderness of the liver. Several consultations were held, and Dr. H. P. Hawkins, Dr. H D. Rolleston, and Mr. Cyril Nitch all saw the patient. Bacillus coli autogenous vaccine was prepared and given in increasing doses every third day, having got up to 5 millions at a dose in three doses, with an increase of 2 to 3 millions each time. The result was disappointing.

Finding that in spite of all treatment the patient was losing ground rapidly, it was suggested through reading the description of "Injection of Sea-water," by Dr. R. Simons, to try the sea-water injection, and with the patient's consent the first injection was given on Sept. 9th, 1910. We began by giving 25 c.c. of sea-water (plasma marina) injected under strict aseptic precaution, in the right scapular region, but finding that it was followed by no discomfort it was subsequently increased from 25 to 50 c.c., and continued twice weekly for 30 injections. The temperature soon began to fall to normal, but at first after each injection it would fall and then rise again to 100° or thereabouts before the next injection was given. This continued for a time until it came down and remained at normal. She began to increase in weight. Sleep became natural, although up to that time it had to be induced by hypodermic injections of morphia. The improvement continued, the stools became formed and regular, appetite gradually improved, and she thoroughly enjoyed her meals, and a more liberal diet was given. The apical murmur disappeared, as did also the anæmic condition. At the end of six weeks she was for the first time able to leave her bed and sit up daily in a chair. Each week she gained on an average a little over ½ lb. in weight. Her weight before the injection was given was 5 st. 4 lb. (74 lb.). At the end of the 30 injections it was 6 st. 8 lb. (92 lb.). After each injection she described herself as feeling much stronger, and they seemed to act as a powerful tonic to her general system. Finally, six months after the beginning of the sea-water treatment, she was able to take out-door exercise and live her ordinary life

This is a case in which drugs and vaccine-therapy seem to have utterly failed. How sea-water acts is purely a matter of conjecture and is an interesting question, but Dr. Rolleston suggests that it would tend to increase the amount of sodium chloride and so keep a certain amount of fluid in the tissues, and therefore would counteract any factor, such as diarrhœa, which produces drying up of the tissues and inelasticity of the skin. It is the converse of the salt-free diet employed for œdema, especially of renal disease. Thus, some conditions—e.g., renal disease—are benefited by privation of sodium chloride, whilst others—marasmus—are benefited by an increased administration of sodium chloride.

In the above case it has acted beyond all hope or expectation, and may almost certainly be said to have saved the patient's life. In certain cases it is undoubtedly worthy of a more extended trial.

Sir Frederick Eve, F.R.C.S. Eng., and Dr. Galloway, F.R.C.P. Lond., have joined the medical board of the Royal Sea Bathing Hospital.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A NOTE ON A CASE OF ANGINA SINE DOLORE AND GASTRIC DEFLATION.

BY H. WALTER VERDON, F.R.C.S. ENG.

THE presence of "risus sardonicus" removes the case from the ordinary category of fainting attacks, and justifies the title of "angina sine dolore." For the reason that but few of these cases find their way into medical literature, the publication of this one will, I believe, prove of interest to readers of THE LANCET.

On the morning of Saturday, May 20th last, a man, aged 63 years, after taking a bath, was seized with a fainting attack and called his wife to his assistance. With her help he put on some light clothing and a dressing gown and went downstairs. While seated at table in the breakfast-room, he complained of feeling very ill, the fainting attack recurred and he fell into a state of semi-consciousness. When I entered the room a short time afterwards he seemed to be dying. The posture of the body indicated collapse. He had sunk into a heap in his chair. His head was resting on one of the arms, and his chin was depressed on his chest. His arms hung listlessly by his sides. His face, neck, and hands were cold, grey, bloodless, and wet with perspiration. No pulse was felt in the radial artery, and respiration had apparently ceased. But for the fact that the muscles of the face were contracted and the jaws clenched I would have come to the conclusion, as his wife had already done, that he was dead.

The sardonic grin distorting the man's features reminded me of a similar expression of countenance often witnessed in persons during the course of an anginal seizure, and in certain cases of this disorder having noticed instant relief follow from deflation of the stomach I proceeded to pass an œsophageal tube. A gap in the wall of teeth at the molar region of the jaws furnished a ready means of access to the throat and allowed me the opportunity of performing the operation without any delay. Upon the distal end of the tube engaging the lower end of the œsophagus, or entering the stomach, I do not know which, it liberated gas in considerable volume, and immediately afterwards the patient was observed to take a deep inspiration. The tube was permitted to remain *in situ* until pulse, respiration and consciousness were fully restored, and then irrigation of the stomach with hot water was practised.

The patient had recently shown signs of heart failure when ascending flights of stairs, when walking on hilly roads, and when engaged in other kinds of strenuous exercise. The pulse had been noticed to show signs of myocardial weakness and intermission even at times of repose. After the seizure the pulse grew firmer than it had been for several weeks past and its rhythm was more even and without intermissions. The patient walked upstairs without the signs of distress to which he is accustomed, and on the following Monday went to town, spent many hours in his office, and attended to his business affairs after his usual custom.

The seizure in this case illustrates the operation of a gastric reflex simulating heart failure and belongs to a category described by me in a paper which appeared in THE LANCET of June 18th, 1910, entitled "A Comparison made between the Simple Gastro-circulatory Seizure and the Angina Pectoris Attack." The pathological conditions underlying this form of seizure and also that of angina pectoris probably consist of increased irritability of the glosso-vagus-accessory group of medullary ganglia, following in the train of a long course of gastric disturbances, hypertension of gastro-mural muscle, and an augmented gastric atmosphere. The immediate cause of the seizure is inhibition of the heart through abnormal vagus stimulation.

The symptom referred to above—namely, the risus sardonicus—besides being occasionally seen during the angina pectoris attack, is of exceedingly frequent occurrence in young infants. It is characteristic of flatulent distension of

the stomach. It is excited by irritation of the glosso-vagus-accessory nuclei which are closely related in the medulla with the nucleus of the fifth cranial nerve, the branches of which innervate the muscles of the lower jaw.

The remarkable result obtained from the passage of the œsophageal tube should have the effect of bringing to the notice of the profession the importance of gastric symptoms in cases of this type, since many cases commonly regarded as illustrations of impairment of the contractile function of the myocardium, among which angina pectoris is usually numbered, are in reality subjects of a gastric reflex.

Streatham-hill, S.W.

A CASE OF MELANOTIC SARCOMA OF THE LIVER, SECONDARY TO A MELANOTIC SARCOMA OF THE EYE REMOVED BY OPERATION TEN YEARS PREVIOUSLY.

BY CHARLES H. LILLEY, M.B., CH.B. ST. AND.,
HOUSE SURGEON, ROYAL DEVON AND EXETER HOSPITAL.

THE patient, a female, aged 46 years, was admitted into the Royal Devon and Exeter Hospital on Nov. 10th, 1910. Since the beginning of May, 1910, she had noticed that, to use her own expression, she was "getting hard in the stomach." She placed little or no importance upon this condition until a month prior to admission, when she began to suffer severe pain in the back and down the legs, which at times were swollen. Later she noticed that she was getting much stouter, and that her clothes were very tight around the waist.

The previous history of the case had a most important bearing upon the diagnosis. In the year 1900 the patient had a tumour of the eye removed at the West of England Eye Infirmary, Exeter, by Mr. A. C. Roper, and on inquiry I found that this tumour was a melanotic sarcoma.

On admission the patient's general condition was remarkably good; she was well nourished and not at all cachectic in appearance. Her right eye had been enucleated, and the socket appeared to be quite healthy. An examination of the abdomen showed the presence of a very large and hard tumour filling the greater part of the abdominal cavity. Its upper limit was represented by a line drawn horizontally across the chest at the level of the fifth rib. Laterally the tumour filled both flanks. It was just possible to get the edge of one's hand between the tumour's lower limit and the pubic arch, and at the middle of the lower border a distinct notch could be felt. The surface of the tumour was nodular in places. The hæmopoietic and other systems were normal. The urine did not darken very much on standing, but on the addition of a few drops of ferric chloride it at once darkened, a black deposit forming. The patient went steadily downhill. The abdomen got progressively larger, increasing in circumference from 34½ to 40 inches. The application of the X rays had no effect in reducing the size of the growth. Later jaundice became a very marked feature and the patient passed into a drowsy, stuporous condition, and eventually died on Dec. 27th—i.e., six weeks after admission to hospital. The temperature throughout had shown an evening rise, being frequently over 101° F. and dropping to normal in the morning.

At the post-mortem examination the liver was found to be enormously enlarged and it weighed 19 lb. 6 oz. in fresh condition. It was very dark in colour. On cutting into the tissue it was found to vary in colour, being coal-black at some places and at others of a greyish-black colour. The growth was diffuse, and only one or two islands of normal liver tissue were to be seen. The difference in colour was doubtless due to the greater accumulation of pigment at some places than at others. The other organs were normal, the liver alone being involved. A microscopical section showed spindle cells with blackish-brown granules deposited in and around them.

I have thought this case of sufficient interest to warrant its being published as illustrating (1) the long period—viz., 10 years—which had intervened between the removal of the primary growth and the secondary invasion of the liver; and (2) the large size to which these secondary growths in the liver may attain.

I have to thank Mr. Roper, in whose ward the patient was, for permission to publish these brief notes.

Exeter.

NOTES ON A RARE CASE OF CONGENITAL HÆMATOMA.

BY SPENCER SHEILL, F.R.C.P. IREL., &C.,
EXAMINER IN MIDWIFERY AND GYNÆCOLOGY TO CONJOINT BOARD OF R.C.P. AND R.C.S. IRELAND.

THE subject was a male child, born early in February of this year, which, on examination immediately after birth, was found to have a soft tumour under one of its armpits. The labour was natural in every detail, although it is true the mother was unusually active in struggling during chloroform administration. The tumour was of about the size of a hen's egg and plainly cystic in character. It was situated in the mid-axillary line about an inch below the axilla. It appeared at first to be affected by respiration, but closer inspection revealed that this "hardening" of the mass was most likely due to the action of surrounding muscles. As well as could be made out, the ribs beneath the tumour were normal. It appeared to cause the little patient no inconvenience other than inability to adduct the humerus to the normal extent, although the child was unduly cross, but that is perhaps too common a complaint to be of value as a symptom. On waiting eight days, as the tumour seemed to be if anything slightly larger, I decided to tap it, and withdrew through a large needle nearly four fluid ounces of what appeared to be almost pure blood of a very dark hue. The tumour collapsed completely and the ribs beneath were palpated as normal. It again began to fill slowly and by ten days had attained its previous size. Two days later I noticed a "pulsating" lump at the side of the neck above the clavicle, but the "pulsation" proved to be a "fluid wave" communicated from the original tumour by arm movements and by respiration; one could easily imitate this by the fingers placed on the tumours above and below the clavicle. All this time there were no palpable glands in the neck or axilla. The mother had cardiac disease, as had also her father and two sisters, but I cannot see in this fact anything to throw light upon the origin of the tumour. Of course, I feared sarcoma and was obliged to give a guarded opinion to the parents. On March 4th, that is, about four weeks after the birth of the child, I noted in my case-book: "Tumour softer and smaller, and bulging above clavicle absent." On March 21st the tumour had entirely disappeared, but what feel like two slightly enlarged glands occupy its site.

I cannot look upon this case as comparable to a sterno-mastoid or other hæmatoma due to violence at birth, and my inability to find records of anything similar in a fairly full search through the literature has prompted me to publish these few notes.

Dublin.

Reviews and Notices of Books.

The Surgery of the Diseases of the Appendix Vermiformis and their Complications. By WILLIAM HENRY BATTLE, F.R.C.S. Eng., Surgeon and Joint Lecturer on Surgery to St. Thomas's Hospital; and EDRED M. CORNER, M.A., M.B., M.C. Cantab., F.R.C.S. Eng., Surgeon in Charge of Out-patients and the Surgical Isolation Wards to St. Thomas's Hospital; Lecturer on Practical Surgery. Second and enlarged edition. London: Constable and Co., Limited. 1910. Pp. 291. Price 10*s.* 6*d.* net.

SEVEN years have elapsed since the appearance of the first edition of this work; in those seven years much has been written about the diseases of the appendix, and the authors have endeavoured to incorporate in the volume the important points of the new material. The effect has been a very natural increase in the size of the volume.

The book commences with a brief history of our knowledge of the affection, and it is pointed out that as long ago as 1711 Heister recognised the relationship between disease of the appendix and diffuse peritonitis. The anatomy of the region of the appendix is carefully described, and the varieties of form and position of the organ are illustrated by diagrams. The authors give good reason for thinking that the appendix is not functionless, but that it is a specialised part of the

alimentary canal, as it has a special development of lymphoid tissue for protection against the influence of the bacteria in the cæcum. The etiology of appendicitis is discussed, and the interesting statement is made that, in the opinion of the authors, there is nothing in the way of exercise that is so potent a factor in producing an attack, when appendicitis is latent, as the riding of a motor-cycle. The suggested dependence of the disease on particles of steel in flour is ably argued. The incision which is advocated is that originally introduced by Mr. Battle, one of the authors, and it is probably for many cases the most satisfactory of all. The use of the clamp for crushing the root of the appendix is also advocated, and those who have employed it agree in its rapidity and value. The question as to the time of operation is discussed fully. An interesting section is that dealing with removal of the appendix in patients who have never had a recognisable attack of appendicitis, but who have had vague pains and have urgently demanded removal of the appendix. In all the cases described marked lesions were found. The tumours of the appendix are described, and subdiaphragmatic abscesses and empyemata resulting from appendicitis are also referred to. Two cases are mentioned in which empyemata followed attacks of appendicitis. Chapters on the peculiarities of the diseases at different periods of life and the diagnosis of tumours in the iliac region are provided; and, lastly, there is a chapter on the important subject of appendicitis in relation to life assurance.

This valuable treatise represents fully the present state of our knowledge of appendicitis, and it may with confidence be recommended to all who wish to study the subject.

Foods and their Adulteration. By HARVEY W. WILEY, M.D., Ph.D. Second edition, revised and enlarged. With 11 coloured plates and 87 other illustrations. London: J. and A. Churchill. 1911. Pp. 641. Price 21*s.* net.

Dr. Wiley's book covers a lot of ground in connexion with the question of foods in general and of their adulteration in particular, as might be expected from his official connexion for a great many years as chemist to the Government of the United States of America. He has been closely associated with far-reaching movements of reform in that country aimed at raising the standard of purity of foods, and in spite of the drastic character of some of the proposals for which he was in part responsible, they have appealed to the State and have been admitted as legislative measures. The opposition was, of course, severe, but it appears to have died down, and we have even heard that a good many of the erstwhile enemies to the proposals have subsequently adopted a friendly bearing to the new food laws and the standards of purity which they contain.

The present work is the second edition. Of the first edition a review appeared in our columns of Sept. 28th, 1907. For the most part the book remains in its original presentation, the work of revision and addition having been applied mostly to Part X., which deals with infants' and invalids' foods. This chapter, we find, has been extended to nearly 100 pages, and an inspection of their contents shows that a valuable addition to the subject matter has been made. A completely new addition consists in Part XI., which sets out some simple methods for detecting food adulterations. Dr. Wiley holds that many forms of adulteration may easily be determined by simple tests that anyone without the training of the professional chemist may practise, using the ordinary apparatus found in the household and reagents which are constantly at hand or which may readily be obtained at the drug store. We do not agree with this recommendation. It is true that the layman may educate himself to detect additions which are of a more or less coarse kind, but the practice of preserving foods—for example, with antiseptics—is not a clumsy proceeding nowadays, but requires a skilled person to lay it bare. We very much doubt if a layman could carry out with certainty the detection of benzoic acid in foods. Moreover, he is instructed to employ chloroform for the purpose, and a layman has no right to be in the possession of this drug. He is recommended to use chloroform also for extracting salicylic acid and saccharin from foods and liquids. The art of preserving foods is getting increasingly subtle and the highly trained chemist requires all his skill to be able to certify that a given article of food is free from objectionable preservatives. It does not suit the manufacturers' or purveyors' business to use a preservative that is easily detected, and the directions here given to the uninstructed in these matters are pretty certain to end in a failure to obtain positive results. The conclusion, therefore, of the household experiment might obviously give a false sense of security.

We attach a much greater value to the series of monographs on special invalid foods, which contain many sound common-sense observations as to their questionable advantages. In this section there is also given an extensive series of analyses of many familiar and widely advertised infants' and invalids' foods and medicinal foods, which presents many interesting points to the medical and analytical practitioner. The general information as to the distribution of various foods and their preparation for the consumer is, further, a valuable asset of the book.

A Manual of Pathology and Morbid Anatomy. By T. HENRY GREEN, M.D. Lond., F.R.C.P. Lond. Eleventh edition, revised and enlarged by W. CECIL BOSANQUET, M.A., M.D. Oxon., F.R.C.P. Lond., Assistant Physician to Charing Cross Hospital. With 350 illustrations. London: Baillière, Tindall, and Cox. 1911. Pp. 642. Price 15*s.* net.

IT is about six years since the tenth edition of this work, which was reviewed in THE LANCET of Nov. 4th, 1905, was issued. The book is now published as one of the "University Series," and is a distinct improvement on its predecessor. The paper is now white instead of a faint yellow, which brings out the illustrations much better. Some of the longer chapters have been subdivided, while the number of illustrations and pages is about the same. As to the text, it has been slightly rearranged, modified, and added to, more especially in the chapters dealing with parasitology, where these changes were necessitated by the recent discoveries of the relation of protozoa to disease and of the part played by spirochætæ in diseases of animals as well as of man. "Parasites" occupy about 120 pages. Some of the advances that have been made in pathological chemistry have been incorporated. We think that the introduction of the dates of certain great discoveries would help to interest the student. A few are introduced in certain chapters under "Parasites," but there is room for more—e.g., the date of the discovery of tubercle bacillus, of John Hunter's famous experiments mentioned in the text, of Reverdin's work on skin-grafting, of Hodgkin's and Raynaud's diseases, and many others. When discussing "fatty changes," perhaps it would have been well to add some of the more recent methods for the staining of fats—e.g., Sudan, Scharlach, Nile Blue, and the use of bichromates in this connexion. While osmic acid is referred to on p. 565, it should have been pointed out that all forms of fat are not stained black by this reagent. We did not find the word "enzymes" either in the text or index. It may, however, be in the former. *Per contra*, acromegaly is referred to in the text, but does not occur in the index. More details might have been given on pentosuria and the effects of adrenalin on the arterial wall. The illustrations in

the nervous system are largely taken from Mott's excellent researches. In Fig. 306, should not "Betts' cell" be Betz's? Two-thirds of the whole is devoted to general pathology and one-third to special tissues and organs. There are no references to original papers. The student of all grades will find that this work will meet his wants.

A Handbook of Intestinal Surgery. By LEONARD A. BIDWELL, F.R.C.S. Eng., Surgeon to the West London Hospital; Lecturer on Intestinal Surgery and Dean of the Post-Graduate College. Second edition. London: Baillière, Tindall, and Cox. 1910. Pp. 215. Price 6*s.* net.

THE importance of the surgery of the intestine can hardly be over-estimated, and we are pleased to see a second issue of this little work, because it contains a system of training in intestinal surgery which is eminently desirable for all who would undertake operative work on the abdomen.

The book arose from a practical class in intestinal surgery which was established at the West London Post-Graduate College. In that class practical instruction is given in the application of sutures to intestines, and for this purpose the small intestine of bullocks is employed, obtained from the slaughter-house on the day the animal is killed. The intestine of the bullock closely resembles human intestine, for its thickness is about the same, while in many of the lower animals, such as the dog, the intestinal wall is much thicker than it is in human beings, and therefore if the intestine of the dog be employed students may obtain a wrong idea of the care which is necessary in certain sutures. Mr. Bidwell has devised an ingenious little intestine holder which takes the place of an assistant. The book will therefore serve as a guide, not merely in the performance of intestinal anastomosis in the laboratory, but also equally well for instruction in the methods to be followed in the operating theatre. The descriptions are extremely clear, and the whole work is of an eminently practical character.

Gehirn und Rückenmark: Leitfaden für das Studium der Morphologie und des Faserverlaufs. Von Dr. EMIL VILLIGER, Privatdozent für Neurologie und Neuropathologie an der Universität Basel. With 224 illustrations, partly coloured. Leipzig: Wilhelm Engelmann. 1910. Pp. 278. Price M. 12.80.

THE physician who would combine the scientific with the clinical side of diseases of the nervous system cannot do better than make himself familiar with the contents of this excellent "Guide." Accuracy of diagnosis depends on a sound knowledge of the anatomy of the nervous system, for there is no other class of disease in which the symptoms are associated less with the nature of the pathological process than with its localisation. Lesions in the central nervous system separated from each other by merely 1 centimetre, or even less, may in certain instances give rise to widely differing clinical pictures. Hence the fundamental importance of nervous anatomy. Dr. Villiger is to be congratulated on the manner in which he has accomplished the task of providing a "key" to the study of the anatomical complexities of the nervous system. While the descriptions in the text are for the most part so lucid and methodical as to reduce possible confusion to a minimum, he has relied on a splendid series of diagrams, of which some are partly coloured. By giving so large a number of them the author has been able to simplify them, and their clearness leaves nothing to be desired. The intricacies of the basal ganglia, brain stem, pons, and medulla are treated in a masterly fashion. The elaborate connexions of the cerebellum are made plain in a series of particularly good diagrams. In a word, this well-printed and well-got-up volume combines the advantages of an atlas with those of a systematic treatise on the subject, yet it is neither too long nor too intricate for the author's purpose, as stated in the preface, and we do not know any equally concise volume in which the matter is so adequately handled. We consider the book, with its schematic and microscopical illustrations, an excellent study of nervous anatomy, and one that may be consulted with great profit by the neurologist.

Das Asthma, sein Wesen und seine Behandlung. (*Asthma, its Nature and Treatment.*) By Dr. BRÜGELMANN, Baden-Baden. Fifth edition. Wiesbaden: J. F. Bergmann. 1910. Pp. 268. Price 5*s.*

Dr. Brügelmann bases the results which he records in this volume on the experience gained by investigations during 32 years into the nature and treatment of asthma. In discussing the etiology and pathology of the disease he maintains that it is invariably brought about by an irritation of the central nervous system, especially of the centre of respiration. He states that he uses the term "central nervous system" advisedly, since the site and exact physiology of the centre of respiration have not yet been accurately determined. He further considers that the classification usually adopted—viz, into spasmodic and bronchial asthma—should be abandoned, since the paroxysms in both conditions are due to the same cause—namely, the central irritation. This irritation, he says, may arise from several causes, and he arranges them into three groups, classifying the cases of asthma according to the nature of the irritation:—1. Traumatic asthma. Here the irritation may arise from injury of the brain by blows, falls, shock, or the influence of cold; also emotional conditions are included under this heading. 2. Reflex asthma. In this group the irritation is produced in a reflex manner, the primary lesion being "asthmatic points" having their rise in the mucous membranes of various regions; also nervous conditions (e.g., neurasthenia) may have a similar action. 3. Toxic asthma. Various toxic conditions of the blood may supply the necessary irritant. The various forms of treatment are discussed at length, and numerous suggestions are made as to the divers methods that may be adopted in the different varieties of the disease.

Those practitioners who are especially interested in the nature and treatment of asthma will find this book interesting. The whole subject is considered in a manner different to that found in other text-books, the arguments used are worthy of consideration, and the portions devoted to treatment give valuable information.

JOURNALS AND MAGAZINES.

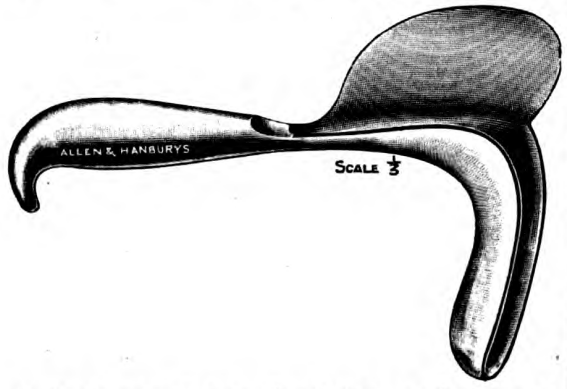
Quarterly Journal of Experimental Physiology. Vol. IV., No. 1, March 3rd, 1911; and Vol. IV., No. 2, June 10th, 1911. Price 6*s.* each part. London: Charles Griffin and Co., Limited.—Dr. J. Argyll Campbell, in his paper on the Effects of Certain Animal Extracts on the Blood-vessels, finds that using suprarenal extract in the form of hemisine by the perfusion method causes marked constriction of the vessels of all the organs with the exception of those of the heart and lungs. Pituitary extract seems to contain two substances, one causing constriction and the other relaxation. Dr. T. Graham Brown continues his studies in the reflexes of the guinea-pig, the present papers being Nos. 6 and 7 of the series. A cognate subject is this author's joint notes with Professor C. S. Sherrington on the pilomotor system Those who are interested in the psychology of the emotions will read with particular interest these "Notes," which are very suggestive in regard to "expression." The paper on narcosis and that on the pilomotor system are illustrated by photographs of the animals used. Dr. George Oliver's paper on two new methods of reading the arterial blood pressure in man will be of interest to medical men. Dr. Sutherland Simpson and Miss J. L. King find that in the sheep the motor area is located in the superior frontal

convolution, and as a corollary may be taken Miss King's contribution on the descending spinal paths in the same animal. The pyramidal tract is comparatively small and cannot be followed beyond the first cervical segment. Mr. W. A. Jolly's observations on the time relations of the knee-jerk and simple reflexes were made on the rabbit, by means of the string galvanometer. Mr. H. E. Roaf's paper is a short one. He finds that in a strip of tissue near the rectal gland in Purpura lapillus there is a pressor substance allied to adrenin. Dr. R. Burton-Opitz of Columbia University contributes three papers (Parts II., III., and IV.) on the vascularity of the liver. For the results we must refer the reader to the original papers. Dr. J. Ritchie and Mr. Ninian Bruce find that in diphtheritic toxæmia in guinea-pigs there is a complete or relative absence of adrenalin and that death appears to result from a condition which might be compared to acute Addison's disease. Dr. P. T. Herring continues his observations on the histology and functions of the pituitary body. In elasmobranchs the secretion is poured directly into the blood-vessels.

New Inventions.

AN IMPROVED VAGINAL SPECULUM.

THE accompanying illustration shows an improved form of Sims's vaginal speculum, which I have found useful. I have added a flange-like projection to the upper blade, which is of considerable assistance when examining patients in the left lateral position. The flange lifts up the right buttock



when the speculum is inserted so that one can dispense with the help of a nurse or assistant and a much better view of the cervix is obtained than is possible with the ordinary form of duckbill instrument at present in use. The speculum has been made for me at my suggestion by Messrs. Allen and Hanburys, Wigmore-street, W.

C. HUBERT ROBERTS,
M.D. Lond., F.R.C.S. Eng., F.R.C.P. Lond.
Welbeck street, W.

ASYLUM REPORTS.

Surrey County Lunatic Asylum at Brookwood (Annual Report for the Year 1910).—The total number of cases treated at this asylum during the year was 1315, the average number resident being 1063. There were admitted 283 cases, of whom 141 were males and 142 were females. 133 cases were discharged, 75 being discharged as recovered, giving a recovery-rate calculated on the admissions, but excluding transfers from other asylums, of 43·69 per cent for the males and 24 per cent. for the females, the total average being 32·89 per cent. There were 72 deaths during the year, a percentage on the daily average number resident of 6·77. The cause of death was verified by post-mortem examination in 93 per cent. of the deaths.

County and City of Worcester Lunatic Asylum at Powick (Annual Report for the Year 1910).—At this asylum the average number resident was 957. The admissions numbered 189, there being 80 males and 109 females. A percentage of 13·2 of the direct admissions had had a previous attack. A history of insane heredity appears to have been obtained in only 3·7 per cent. Sixty-seven persons were discharged during the year. Of this number 15 males and 24 females were discharged recovered, being a rate of 25·8 on direct admissions. Sixty-three persons died, and post-mortem examinations were made in 52 cases. The chief causes of death were: phthisis, 20·6 per cent.; heart disease, 12·7 per cent.; Bright's disease, 11·1 per cent.; and old age, 24 per cent.

Derby Borough Asylum (Annual Report for the Year 1910).—The daily average number resident at this asylum was 357. The number of patients admitted was 84. The general health of the patients admitted was found to be very unsatisfactory, and the medical superintendent, Dr. S. Rutherford Macphail, remarks that in many cases the mental condition was complicated with bodily disease of a serious nature, no less than 69 per cent. being found to suffer from recognisable physical disease. One-fourth of the patients admitted had organic heart disease. Inquiry revealed the occurrence of actual insanity among near relations in 40 per cent., while in several others mental and physical defects indicating degeneration were observed. Thirty-six patients were discharged, 30 as recovered. The recovery rate was 45·45 per cent. of the admissions, excluding transfers, and 6·90 per cent. of the total number under treatment. The number of deaths was 23, being a percentage of 6·44 on the daily average number resident. The average age at death was 54 years. The death-rate is the lowest in the history of the asylum. Post-mortem examinations were made in every case. General paralysis was found to be the cause of death in 23·8 per cent., phthisis in 7 per cent., and senile decay in 9·5 per cent.

Bucks County Asylum at Stone (Annual Report for the Year 1910).—The average daily number on the register at this asylum was 665. There were admitted 210 patients, 91 being males and 119 females. Of those admitted, and excluding congenital cases, 110 were first-attack cases, while 36 had suffered from one or more previous attacks. An insane heredity was ascertained in 47 cases, or 28 per cent. Altogether 94 patients were discharged, of whom 66 had recovered, giving a recovery rate of 43·7 per cent. for males and 36·9 per cent. for females calculated on the direct admissions. The death-rate was 9·3 per cent. of the average number resident, as compared with 12·2 of last year. The death-rate from tubercle was low, being 6·4 per cent. of all causes. A female patient died at the age of 74, after 57½ years' residence.

Monmouthshire Asylum at Abergavenny (Annual Report for the Year 1910).—At this asylum the average number resident was 951. There were admitted 174 patients, of whom 100 were males and 74 were females. Seventy-seven patients were discharged, and of these 54 were discharged as recovered. The recovery rate for the year, calculated on the total number of admissions, was 31 per cent., or 22 per cent. for males and 43·2 per cent. for females. This rate is 5 per cent. lower than the average rate obtained since the opening of the asylum and is accounted for by the very low rate among the male patients which arises from the unfavourable character of these cases on admission. The deaths numbered 75, and the rate, calculated on the average number resident, was 7·8 per cent. Post-mortem examinations were made in 77 per cent. of those who died.

City of London Asylum at Stone, near Dartford (Annual Report for the Year 1910).—The average daily number resident at this asylum was 589. There were 164 admissions. Discharges were 94, of which 31 were recoveries, being a proportion per cent. of 24·2 on the direct admissions. Deaths numbered 43, and 29 necropsies were made. The percentage of deaths was 7·30 on the daily average number resident. The medical superintendent, Dr. R. H. Steen, reports that the death-rate from consumption on the average number resident was only 3·4 per 1000, and he inclines to attribute this to the situation of the asylum upon a chalk hill and to the open-air life led by the patients. Verandahs are in use throughout the whole year for cases of mental disorder requiring treatment by means of rest in bed. Patients appear to become much attached to sleeping in the verandahs, and when, owing to severe weather, their removal indoors was contemplated, a storm of opposition arose.

THE BRITISH MEDICAL ASSOCIATION.

SEVENTY-NINTH ANNUAL MEETING IN BIRMINGHAM.

THE annual dinner of the Association was held on the evening of July 27th, in the spacious hall of the Grand Hotel, with the new President in the chair. There were nearly 250 members and guests present, and the banquet was in every way a great success. The company included the Bishop of Birmingham, Lord Ilkeston, the Lord Mayor of Birmingham (Alderman W. H. Bowater), Sir Oliver Lodge, Mr. Neville Chamberlain, Sir John Holder, Mr. L. S. Amery, M.P., Mr. J. T. Middlemore, M.P., Sir James Barr, Sir Francis Lovell, Sir James Sawyer, Professor Strassmann of Berlin, Professor R. A. Reeve, Professor Stoeltzner, Professor Vogt, Dr. Byrom Bramwell, the principal office holders in the Association, and seven or eight lady members, including Dr. Mary Scharlieb and Dr. May Thorne. After the loyal toasts had been honoured the Bishop of Birmingham proposed the toast of "The British Medical Association," and spoke of the sympathy between the clergy and the medical profession. Both callings were much criticised, and both were often accused of considering class interests when they were really upholding the best interests of the nation and of humanity. Dr. Ewen J. Maclean, the chairman of representative meetings, in responding to the toast, spoke of the Association's work in connexion with the National Insurance Bill. For the first time in its history the profession had come in contact with the political machinery of the country. The Association, by keeping to the front line of its policy, had secured much already. If it adhered to its demands it would enable the medical profession to do its duty both as doctors and as citizens. Mr. Amery, the Member for South Birmingham, in proposing the toast of that city, spoke of Mr. Chamberlain's services to medicine. With reference to the Insurance Bill, he agreed with those medical men who doubted whether "doctoring in abundance and doctoring on the cheap" was the best way of attacking the problem of the public health. He said that all medical men wished to support a scheme which would not lower professional standards. The Lord Mayor responded in a humorous speech which delighted the company. Professor Gilbert Barling gave a graceful welcome to the guests of the evening. Of Lord Ilkeston, he said that the profession looked to him for help when the Bill reached the House of Lords, and hoped that he would so guide that assembly in the matter that wisdom and justice would prevail. Professor Strassmann and Mr. Middlemore responded on behalf of the visitors, and thanked the Association for its hospitality and congratulated it on the scientific and social success of the seventy-ninth annual meeting. The health of the President was warmly proposed by Mr. Neville Chamberlain, and after Professor Robert Saundby had replied, a very pleasant gathering broke up.

The summer general meeting and luncheon of the Irish Medical Schools and Graduates' Association was held on July 26th, at the Imperial Hotel, Birmingham. In the unavoidable absence of Sir Charles Cameron, C.B., Dr. Macnaughton Jones took the chair. The luncheon was a very successful one, and there was a large attendance, including ladies.

On Thursday, July 27th, a special Honorary Degree Congregation in connexion with the visit of the British Medical Association was held at the University at Bournbrook in the afternoon, when the honorary degree of Doctor of Laws was conferred upon Mr. John Burns and upon eight distinguished medical men. The Principal of the University, Sir Oliver Lodge, in presenting the recipients of these degrees to the Vice-Chancellor, made in each case a brief speech of welcome and introduction. Besides the President of the Local Government Board, the degree was conferred upon Dr. Byrom Bramwell of Edinburgh; Professor R. H. Chittenden of Yale; Sir Francis Lovell, President of the Section of Tropical Medicine; Dr. J. A. Macdonald, Chairman of Council of the Association; Dr. H. Oppenheim and Dr. Paul Strassmann of Berlin; Professor R. A. Reeve of Toronto; and Professor Sims Woodhead of Cambridge. After the Congregation many of the visitors stayed to inspect the handsome new buildings of the University of Birmingham.

In connexion with the annual meeting, the National Temperance League held its forty-third annual breakfast conference at the Grand Hotel on Thursday morning, July 27th, under the presidency of Professor Robert Saundby. The company numbered nearly 200, and several interesting speeches were made.

On Saturday, after the formal and scientific proceedings in Birmingham were over, the President and a number of members paid a visit to Warwick and Leamington, at the invitation of the mayor and corporation of Leamington and the local division of the Association. Warwick Castle was visited, and the guests were entertained to luncheon at the Leamington Town Hall under the chairmanship of the mayor, Dr. Harold Mason. On the same day a large party journeyed to Droitwich to inspect the brine baths. The party were first conducted to the brine bathing establishments, where the mayor received them. Here the several forms of treatment were explained by the resident medical officers and the manager, and many of the party used the swimming baths. Subsequently 150 guests were entertained to luncheon in the Salter's Hall by Lord Cobham and Mr. Willis-Bund. Other very pleasant excursions were made during the week to Lichfield, to Lady Warwick's Horticultural College for Women at Studley Castle, to Coventry, to Stratford-on-Avon, to Hereford, and to Malvern and Worcester. The arrangements were good, and many members and ladies took the opportunity to visit these interesting places in the fine weather which prevailed throughout the whole meeting.

As on previous occasions, we wish to record our thanks to the executive officers of the British Medical Association, and to the Editor and staff of the *British Medical Journal*, for many acts of courtesy and consideration shown to us during the course of the annual meeting.

THE SECTIONS.

MEDICINE.

WEDNESDAY, JULY 26TH.

President: Dr. A. H. CARTER (Birmingham).

The PRESIDENT wished to associate the officers of the Section with the general welcome offered to members and guests on their visit to Birmingham. He also expressed his indebtedness to those who were taking part in discussions or reading papers before the Section. He thought the annual meeting of the Association was not an ideal place for the presentation of new and original work owing to the short time available for each paper and the many distractions offered, but it afforded an excellent opportunity for discussions on clinical problems of every-day experience, and it gave practitioners an opportunity to bring themselves abreast of the times in matters of practical interest.

A discussion on the subject of

Asthma: its Varieties and Treatment,

was opened by Dr. GEORGE ALEXANDER GIBSON (Edinburgh)

who began by stating that the subject was one of special interest since the condition of asthma was dramatic in its symptomatology, elusive in its pathology, and uncertain in its therapeutics. He first outlined the anatomical relations and the physiological mechanisms of the respiratory system. He pointed out the importance of the upper air-passages as a means of warming and purifying the air breathed, constituting a defensive mechanism against noxious agencies. The particular importance of the large amount of erectile tissue in the nasal fossæ in regard to the pathology of asthma was then referred to, and the striking part it played in certain types of the disease was mentioned. The next important facts brought forward were that the larger respiratory tubes were practically rigid and for the most part devoid of muscular tissue, whilst the smallest tubes contained muscular tissue, which appeared to be without tonus under ordinary conditions. He pointed out that cilia were to be found in the respiratory passages, except in the last ramifications of the bronchi. In discussing the nervous mechanism of respiration, he referred to the fact that practically every afferent nerve possessed the power of modifying respiration and that the efferent fibres were contained in the fifth, seventh, ninth, tenth, eleventh, and twelfth cranial nerves and in the spinal roots. The important work of Dixon and Brodie had demonstrated that the muscle in the finest bronchial tubes was under the influence of fibres in the vagus nerves which conveyed both constrictor and dilator influences. He mentioned the interesting observations of Dr. Watson Williams, which suggested that there occurred a rhythmical contraction and dilatation of the finer bronchial tubes, the contraction occurring with expiration, the dilatation with inspiration. He then reviewed the theories which had been put forward to explain the asthma paroxysm, beginning with the view originally put forward by Cullen, and adopted and expanded by Laennec, that it was due to spasm of the finer bronchial tubes. Other theories attributed the paroxysm to weakness of these muscular fibres, to spasm of the diaphragm, and to a vasomotor neurosis as suggested by Traube and Weber. Sir Andrew Clark had adopted the view of a vasomotor neurosis, and believed that in addition there occurred a condition in the mucous membrane of the bronchi analogous to urticaria of the skin. Curschmann had put forward the view that there was a condition of bronchiolitis exudativa. Dr. Gibson believed that recent work proved that the old view of Cullen was the correct one. He wished clearly to differentiate between true asthma and some forms of secondary dyspnœa which counterfeited it, and in this connexion he read a letter which he had received from Sir T. Clifford Allbutt protesting against the current confusion of nomenclature caused by such expressions as cardiac asthma. Dr. Gibson associated himself with this protest and maintained that there was but one asthma. In his view all true asthma was neurotic in origin and must be distinguished from dyspnœa due to toxic causes or to the cyanosis of cardiac disease. In true asthma there might be additional factors, but the principal point remained that it was a neurotic affection. Dr. Gibson had been struck with the periodicity in the incidence of attacks of asthma, and he believed that there was a rhythm which dominated the attacks. He suggested that some *materies morbi* might be stored up and give rise to the attacks explosively. He referred to the direct effects of grief, anger, and other emotions in precipitating the attacks, and also mentioned a case of Heberden's in which asthmatic paroxysms occurred in association with an exostosis pressing on the vagus nerve, and another case in which the same condition resulted from a neuroma of that nerve. The effect of various agents, such as fog, the pollen of grass, the scent of a cat, upon the mucous membrane of the air passages in bringing about the paroxysm reflexly was then discussed. The fact that irritation of the digestive tract, the urinary organs, pelvic viscera, and skin might act in a similar manner was brought out. Dr. Gibson then enumerated the effects of asthma—viz., the over-distension of the lungs, emphysema of the compensatory type, and later of the large-lunged variety, the sclerosis of the pulmonary vessels, and distension of the right side of the heart. He pointed out that all these results had been reproduced in experiments. He believed that the explanation of the distension of the lung was that expiration was incomplete, being interrupted by another inspiration. In regard to treatment, he counselled careful watching of the digestive system, securing thorough excretion, and maintaining the circulation in a condition of adequacy. Catarrh of the respiratory tract was to be prevented. Climatic treatment was difficult. In matters of diet food which was easily assimilated should be given, and distension of the stomach was to be avoided. In regard to drugs, it was known that muscarine would cause asthma, while atropine would stop it. Chloroform, ether, and atropine were stock empirical remedies for which experiment had established a real basis. Morphine stopped the paroxysms at once, but Dr. Gibson, while he admitted using it occasionally, confessed that he did so not without fear. Lobelia was useful, but its effects were short in duration. Nitrites served to relieve spasm. Cocaine was used, but he pointed out the dangers attending its use, and he believed that it should be employed with the greatest reservation. He believed that suggestion might be helpful in neurotic patients.

Dr. R. SAUNDBY (Birmingham), the President of the Association, accepted the view that asthma was a neurosis, but thought Dr. Gibson had narrowed this conception unduly. Dr. Saundby believed that there was reflex spasm, mainly of the respiratory muscles, with spasm of the smaller bronchioles and turgescence of the mucous lining. He referred to recent observations upon anaphylaxis in asthma, showing that asthmatic patients were particularly liable to fatal anaphylaxis after ordinary doses of diphtheria antitoxin. He thought this suggested an analogy of the bronchial changes with the urticaria which also occurred after diphtheria antitoxin. He mentioned the class of cases cured by such measures as removing polypi from the nose, but stated that in many asthmatics the causative agent was unknown. He quoted cases where locality played an important part and referred to some caused by emanations from animals and from furs. In connexion with diet he advised small meals and easily digested food. A purin-free diet was well worth trying for a time. He believed that the periodicity described by Dr. Gibson accounted for some drugs obtaining a fictitious reputation. Asthma was often a family disease, but might be acquired, sometimes after influenza. In regard to treatment he described the use of iodides. He had found the fluid extract of grindelia of more value than lobelia. He had no confidence in the nitrites, and referred to the use of adrenalin. Asthma powders were sometimes useful, and sprays, though only palliatives, gave encouragement to the patients.

Dr. SAMUEL WEST (London), while accepting the results of physiological experiments, thought there was much which prevented our accepting any theory as entirely adequate. He thought there was a more widely spread condition in asthma than mere spasm of the bronchial tubes. He pointed out that there was a real analogy with epilepsy, and he suggested that asthma was a central rather than a peripheral neurosis. He urged that age was a very important consideration, and stated that so-called asthma beginning in later life raised a strong presumption that it was really one of the forms of secondary dyspnœa and not true asthma. In regard to diagnosis, he pointed out that in children paroxysmal attacks closely resembling asthma occurred as a result of irritation from enlarged bronchial or mediastinal glands, and in adults the condition of plastic bronchitis gave rise to periodical paroxysmal attacks, which were readily cured by iodide of potassium.

Dr. WILLIAM HUNTER (London) employed potassium iodide chiefly in the treatment of the disease. He referred to the use of nitrite of amyl. He thought the spasm was the essential feature in the paroxysm and was of more importance than the congestion.

Dr. T. STACEY WILSON (Birmingham) thought there were risks in the use of nitrites in conditions of bronchial spasm. He suggested that this spasm in capillary bronchitis and in asthma might exert a protective function.

Dr. WILLIAM EWART (London) thought the causation of asthma was always peripheral, and that the first and main factor was contained within the sphere of the vagus. The causation was so varied that there could be nothing specific about the spasm, and he therefore could understand the success of treatment along divergent lines. He discussed the value of powders, and believed that the carbon dioxide in the smoke was a factor in their usefulness, since this substance promoted expiration.

Dr. O. F. F. GRÜNBAUM (London) referred to the use of

vaccines in the treatment of asthma. He had seen cases benefited by this means, but the presumption was that vaccines would only be of use in cases with chronic bronchitis.

The PRESIDENT of the Section, while agreeing that the term asthma should be used in a strict nosological sense, thought Dr. Gibson had been a little severe on those who used it in a symptomatic sense. He urged that in regarding asthma as a neurosis they should be quite clear what they mean by a neurosis. He defined it as a condition of nervous instability. He counselled the adoption of measures to improve the stability of the nervous centres. He believed that a meat diet increased nervous irritability.

Dr. GIBSON replied.

A paper was read by Dr. J. DOUGLAS STANLEY (Birmingham) on

Lung Syphilis.

He pointed out that although pathologists recognised syphilis of the air passages, clinicians showed reluctance to diagnose it. Strümpell had said that no definite clinical description of pulmonary syphilis could be made. There was reason to believe that syphilis and tubercle might coexist, and there appeared to be a predisposition on the part of the syphilitic patient to contract tubercle. This was doubtless to blame for errors in diagnosis. In his paper he confined himself to acquired syphilis. In a series of 1000 cases notified as phthisis he had found two certain cases of syphilis and one doubtful one. In the last seven years he had collected 15 cases, some of which were still under observation. The lesions of syphilis might affect the lungs and pleura only, or the trachea and bronchi, or all of these. Lesions due to secondary syphilis were not of much clinical importance, but ought not to go unrecognised. He described a case in which laryngitis and pleurisy occurred in the secondary stage. In the tertiary stage the trachea was particularly liable to undergo ulceration, and this ulceration might go on to perforation or produce very marked stenosis. The main bronchi might be affected and similar effects might be produced, but the most marked clinical effect was the liability to bronchiectasis. As regards the lung tissue various effects were described, the early changes being an intense cell proliferation filling the alveoli and infiltrating the surrounding structures. The vessels showed the typical changes of syphilis. The process was fairly rapid and was in effect an acute interstitial pneumonia. The next variety described by Dr. Stanley was an early diffuse sclerosis. The lung in these cases was tough and showed great increase of connective tissue. Miliary gummata were plentiful. There was marked proliferation of the elastic tissue. This process was a result of the previous one. The third form was a dense sclerosis. The lung might be contracted and misshapen. Miliary gummata and vascular changes were common. Coarse gummata may occur in syphilis of the lung, but Dr. Stanley had not seen them without some of the other lesions described. The symptoms and signs produced in lung syphilis were illustrated by descriptions of cases. They were much more definite when the lesions were more chronic. Hæmoptysis occurred, and was more suggestive of slow ulceration of a bronchial surface owing to its muco-sanguineous appearance. Cough was irregular and often paroxysmal. Pyrexia, sweating, and wasting occurred and were due to mixed infection. They helped in the imitation of phthisis by syphilis. Signs more marked round the root of the lung or in the interscapular region should suggest a syphilitic lesion, given other indications of syphilis. The constantly negative result of examinations for tubercle bacilli was of great importance in diagnosis.

Dr. HUNTER stated that he had not seen a case of this condition in 1000 post mortem examinations which he had made. He agreed that the fact that cases of syphilis of the lung tended to become tuberculous increased the difficulties of diagnosis.

Dr. LAURISTON E. SHAW (London) stated that he had seen in museums similar specimens to those described and shown by Dr. Stanley, but he had not found them in his own post-mortem experience. He thought the explanation might be that syphilis was becoming less frequent in London than it was formerly.

Dr. WILSON and Dr. SAUNDBY both took part in the discussion, the latter affirming that visceral syphilis was rare in Birmingham.

Dr. STANLEY replied.

SURGERY.

WEDNESDAY, JULY 26TH.

President, Sir THOMAS F. CHAVASSE (Birmingham).

The PRESIDENT expressed the great regret that was felt at the loss of Mr. Furneaux Jordan; even at the last meeting of the Association in Birmingham he had retired from practice, but he would always be remembered as a lucid teacher and a skilled surgeon, who had reflected much credit on the Birmingham Medical School.

A discussion was opened by Mr. J. RUTHERFORD MORISON (Newcastle) on

The Treatment of General Septic Peritonitis.

He said that it had been calculated that the extent of the peritoneum was almost equal to that of the skin, and just as shock and rapid death might follow an extensive scald of the skin, so the same result might follow the injury to the peritoneum produced by general septic peritonitis. The cause of the condition was always an invasion of the peritoneal cavity by pyogenic organisms through some gross channel; and the most frequent cause was appendicitis or rupture of a gastric or duodenal ulcer. Microbically it might be said that the cause was generally a streptococcus. Death was most commonly the result of toxæmia, and it might prove fatal in a few hours. The terminations of septic peritonitis were the same terminations as those of inflammation elsewhere, and they were resolution, fibrosis or destruction and gangrene. If an arm was too tightly bandaged one of these results might follow: the arm might recover completely or it might undergo fibrosis causing Volkmann's ischæmic paralysis, or gangrene might occur. At first attempts to treat by operation general peritonitis were very extensive, and the more extensive they were the more quickly the patient died. The discovery of the germ causing the disease has in no way aided in the cure of the patient, and for surgical purposes the name of the organism present was of little avail; and the results were determined more by the circulatory disturbance produced than by any specific microbic action. Beyond arrest of the supply of germs by removal of the primary focus, surgery could do nothing except by dealing with the results. Knowledge of the condition of the general and local circulation was of more importance in prognosis and treatment than of the name of the organism producing the mischief. The prognosis was good if the heart was strong and the reaction satisfactory and the pulse was under 100; but if the patient was collapsed and the extremities were cold the prognosis was bad. They might speak of toxæmia, but they knew very little of what toxæmia was. Anything which disturbed the balance between the splanchnic and general circulations led to serious symptoms. The peritonitis was a natural reaction to the injury. The peritoneum was not so sensitive to and helpless under injury as used to be thought. It had great resisting power, greater than that of the more superficial tissues. The free secretion of peritoneal fluid was of great value, and the omentum was of important service as a life-saving agency. The mortality of general peritonitis had much decreased of late years, and the chief factor in the marked improvement of results came from an earlier diagnosis of the cause and more prompt treatment. Figures were produced showing the results of the treatment of all cases of peritonitis admitted to the Royal Victoria Infirmary, Newcastle, during the year 1910. There were in all 427 cases with 18 deaths; 33 of the cases were associated with general septic peritonitis, and of these 25 were operated upon; 13 recovered and 12 died. Eight were not operated upon, and of these 2 recovered and 6 died. To show the great importance of removing the primary focus the following case was related. A woman who had had seven children endeavoured to procure abortion at the third month of pregnancy by introducing a crochet hook into the uterus; the hook broke, and two days later she was admitted into Newcastle Infirmary with severe abdominal pain and a pulse of 120. The cervix was divided to facilitate examination and the remaining half of the needle was removed. Vaginal hysterectomy was performed, and the uterine peritoneum was found to be raised in bullæ. The patient recovered. The special and only reason for operation in general septic peritonitis was to deal with the infecting focus. In nearly every case immediate operation was needed, but it should be

performed in a properly equipped hospital or nursing home. Removal rarely made the patient worse. There were three great depressing factors: 1. Exposure; it was important to keep the patient warm. 2. The anæsthetic; as little as possible should be given and for as short a time as possible. It was better to begin with chloroform till the laryngeal reflex was lost and then to give ether. 3. Excessive manipulation; it was extremely important to handle the intestines as little as possible, for if there was rough manipulation the amount of shock was increased. The incision that was best was either a vertical incision in the middle line or an oblique incision in the line of the fibres of the external oblique muscle. It was well not to make the incision through the deeper tissues so extensive as through the more superficial structures; thus made it was more easy to sew up, and when stitching the peritoneum above the umbilicus the stitches should pass through the posterior layer of the sheath of the rectus. When a tube which had been used for drainage was removed a stitch should always be put in, for if not there was risk of bowel becoming strangulated in the opening. As to the site of the incision, as a rule it should be over the centre of the lesion, but if the site of the lesion was unknown the abdomen should be opened by a median incision with excision of the umbilicus. Gauze if used for drainage should never come in contact with the small intestine. After removal of the septic focus recovery depended upon the reaction of the peritoneum. Washing out the peritoneum was a method for which they were indebted to Lawson Tait; it was the best method to use when the peritoneum had to be cleansed. Diffused extravasated contents should be washed out if little or no gross evidence of peritonitis existed. Washing out and drainage might prevent residual subdiaphragmatic and pelvic abscesses. Mopping out was useful, and the sponges should be wrung out of normal saline solution. In most cases neither washing nor mopping was needed. Murphy neither washed nor mopped, and yet his mortality was less than 4 per cent. in cases dealt with within 48 hours. For general septic peritonitis only pelvic drainage was required, the patient being put in the Fowler position. Intravenous injection of saline solution was sometimes of much value, but it should be limited to two pints. The dressing should be voluminous, for it retained the body heat. In the after-treatment Murphy's proctoclysis was of the greatest value. Morphine might be used if employed wisely after the operation, for it might enable the patient to sleep. Purgatives might sometimes be needed. Though early operation was the treatment of an overwhelming majority of cases of septic peritonitis, yet in some it might be a serious mistake. It was likely to be so when the infective focus could not be removed—for example, in pneumococcal and gonococcal peritonitis—and it might also be so after the infective focus had been shut off by a "natural cure."

Professor C. F. A. KOCH (Groningen) said that on most points all surgeons were agreed. All cases should be operated on as soon as possible, unless the case was moribund. He held that the recent improvement in the statistics was entirely due to the appendix cases, for if they excluded these the results were much less favourable. At Groningen the cases were often seen very late, when little could be done for them. It was important to teach both medical men and patients the importance of early operation. If the cause was known the incision should be made near the site of the lesion, and most commonly this was in the right inguinal region. He had employed both flushing and sponging and had not been able to find any difference between the results. He had devised a special drainage-tube which was not easily blocked. In general septic peritonitis two or three incisions for drainage should be made. He had found appendicostomy of great value for supplying fluid to the large intestine. The most troublesome symptom after operation was persistent vomiting, and this he had treated successfully by drainage of the stomach by a tube passed through the nose.

Mr. HERBERT J. PATERSON (London) said that it ought to be acknowledged that much of the recent improvement in results was due to the teaching of American surgeons. The policy of waiting was unfortunately of London origin, and led to harmful results. Pneumococcal peritonitis was very unfavourable, while the gonococcal form was very favourable, and was easily diagnosed. Some of the very chronic cases should not be operated on. He expressed himself as an uncompromising opponent of irrigation of the peritoneum, and he did as little mopping as possible. As to the anæsthetic, he never used chloroform, and he thought it might be quite enough to turn the scale the wrong way in doubtful cases. He considered that the evils of catharsis had been greatly exaggerated, and he gave calomel in small doses by the mouth.

Mr. G. P. NEWBOLT (Liverpool) expressed his surprise at the different statistical results of different surgeons. He objected to chloroform, preferring ether by the open method. It was true that some cases should not be touched, but it was very difficult to say which those cases were. He urged that the surgeon should always be on the look-out for a subdiaphragmatic abscess. A sixth of a grain of morphine after the operation did no harm and might give great comfort to the patient.

Mr. J. GRANT ANDREW (Glasgow) said that he operated in these cases by making an inch-long incision above the pubis, and by the material pouring out learned much as to the source of the peritonitis, and he often knew where to make the main incision. In cases of acute gangrenous appendicitis he excised the appendix, but he did not find it necessary to drain. He raised the head and shoulders of the patient and aspirated the exudation through the suprapubic wound.

Mr. H. GILBERT BARLING (Birmingham) considered that the name, general septic peritonitis, was often misused, and it should only be employed when the whole peritoneum was infected up to the diaphragm and down to the pelvis. The streptococcal infection was the most serious. The skin incision might need to be long when the abdomen was fat, but the deeper tissues need not be more widely divided than usually. The mechanical arrangement of the abdominal organs had much to do with the spread of sepsis. In his opinion both irrigation and swabbing had their uses, but no attempt should be made to remove solid exudate. He was opposed to a routine immediate removal of an appendix.

Dr. J. CRAWFORD RENTON (Glasgow) said that he made a suprapubic drainage opening in cases of ruptured gastric ulcer and also an opening in each loin, and irrigated until the fluid ran through clear. In removing a patient to a nursing home or hospital he kept him in a sitting position. He always gave extract of the pituitary gland to prevent shock. In bad cases the patient had only three or four whiffs of chloroform and then ether. If the patient was kept sitting up after the operation vomiting did not occur.

Mr. GARNETT WRIGHT (Salford) was opposed to removal to hospital of cases with severe peritonitis, though early cases might stand removal well. If the case was advanced the patient stood a better chance at home. In operation for general peritonitis it was important to do the minimum, only just enough to remove the cause. In most cases both washing and mopping were harmful, for they prolonged the operation. When the arrangements did not permit proctoclysis, the intermittent injection of salines into the rectum might prove useful. In all cases he favoured immediate operation.

Mr. C. P. CHILDE (Portsmouth) held that if the general condition of the patient was good the prognosis was good, for it showed that the power of resistance was good. The operation should always be done as quickly as possible. As soon as the peritonitis was recognised the patient should be put into the Fowler position and moved to the operating theatre in that position. A cotton-wool jacket diminished shocks. In some early cases it was not necessary to drain, but generally drainage was needed. Proctoclysis was of great value. If fluid was returned by the bowel it was generally because it was wrongly given. The abdomen should not be tightly bandaged. In acute cases vaccines were of no value, as they could not be obtained in time. In appendicitis he always operated as soon as he saw the patient.

Mr. E. STANMORE BISHOP (Manchester) held that all surgeons were agreed that the earlier the operation the better. He pointed out that the eye, the joints, and the peritoneum had many points of resemblance, and that just as rigidity of the muscles round a joint was often the first sign of joint disease, so rigidity of the abdomen was often the first sign of peritonitis. Morphine just before an operation diminished the amount of anæsthetic needed. As to drainage, common-sense must be the judge. If extensive extravasation of intestinal contents had occurred drainage must be required. It must not be forgotten that drainage tubes ceased to drain after 48 hours, as they became shut off by adhesions. The Fowler position was very uncomfortable, and a less sitting

position was much more agreeable, but the pelvis must be the lowest point.

Mr. LEONARD A. BIDWELL (London) laid stress on the value of the pituitary extract after operation as it restored intestinal peristalsis, and it might counteract the constipating effect of morphine. He never washed out the peritoneal cavity until full drainage had been provided in both loins and in the pelvis. He drained in all cases which had lasted more than 12 hours before the operation. He had a high opinion of the value of a rectal drain.

Mr. D. P. D. WILKIE (Edinburgh) claimed that the organism present was not of so much importance as the patient's resistance. He had found that in fatal cases of general peritonitis there was much distension of the upper part of the jejunum. He had tried the introduction of oxygen gas into the peritoneal cavity and he found that it improved the pulse and caused active hyperæmia of the peritoneum. He had also employed in seven cases the serum from a patient recovering from general peritonitis, and in two cases which seemed certain to end fatally the patients recovered.

Dr. F. MILNES BLUMER (Stafford) related a case of a boy on whom he had operated four times, and on several occasions much septic infection of the peritoneum had occurred and yet the boy had recovered. He considered that the peritoneum did not receive sufficient credit for its power of dealing with septic organisms.

Mr. MORISON, in reply, said that he could not define general septic peritonitis. He agreed that statistics as a rule were very unreliable, but those he had offered were trustworthy.

DERMATOLOGY.

WEDNESDAY, JULY 26TH.

President, Dr. JAMES GALLOWAY (London).

Before the meeting of the Section many cases of dermatological interest were shown, and among them the following may be mentioned:—By Dr. W. A. LOXTON: Multiple Lupus; Lupus Erythematosus; Seborrhœic Alopecia; Ichthyosis in a girl of 15, in whom it first appeared at the age of 5 years; and a case of Lupus of the Leg in a child 10 years old (it had been treated successfully with a 5 per cent. ointment of tuberculin). By Mr. E. GILBERT SMITH: A case of Lupus Vulgaris; two cases of Lupus Erythematosus; a very Typical Syphilitic Ulcer of the Leg; and a case of Erythema Circinatum. By Dr. A. DOUGLAS HEATH: Two cases of Favus in Sisters; Dystrophy of the Nails (possibly due to a Tinea); Adenoma Sebaceum; Lupus Erythematosus; and a case for Diagnosis, which may have been Mycosis Fungoides, or perhaps a Multiple Keloid.

The PRESIDENT opened the meeting with a few words, expressing the value of the subjects about to be discussed and the importance of the exhibition of clinical cases.

Dr. T. COLCOTT FOX (London) then opened a discussion on

The Vascular Disorders of the Skin and their Relation to Other Morbid States.

He gave a *résumé* of the etiology and pathology of the three great groups of symptomatic eruptions in which the blood-vessels are specially involved—namely, the erythemata, purpura, and some phases of urticaria. He ascribed these skin manifestations to the influence of toxins, derived from various sources, circulating in the blood. In many of these conditions a positive diagnosis was at first impossible, yet the answer to the question whether an eruption was a manifestation of a specific fever such as scarlet fever or merely an erythematous condition was of the greatest importance. The evidence in favour of the theory that lupus erythematosus was of toxæmic origin was then discussed. He agreed that in a certain proportion of the cases some tuberculous lesion could be found in the body, but this was often nothing more than a tuberculous gland, and on the other hand it was certain that in many cases not the slightest evidence could be produced in favour of the presence of tuberculous disease either before or after the appearance of the erythematous lupus.

Sir WILLIAM OSLER (Oxford) dealt with those erythematous conditions which were associated with, and probably gave rise to, abnormal visceral conditions. The very same cause might at different times in the same individual produce different lesions, but lesions belonging to the same group of skin affections. Gastric or renal complications might occur, but the latter were much more serious than the former. Even acute nephritis might be seen. Thoracic complications were also met with, such as endocarditis and pleurisy. Sometimes cerebral complications such as hemiplegia and coma had been seen.

Sir MALCOLM MORRIS (London) divided the erythemata into two groups—those which were transient and those in which the course was prolonged. In many of the transient cases the diagnosis was extremely difficult, such as erythema scarlatiniforme, and time was necessary for diagnosis; in such cases it was advisable to isolate the case and to say that as yet a diagnosis was impossible. The time of the empirical treatment of these cases of erythema by aperients had gone by. The explanation of the origin of many of these cases had to be sought in idiosyncrasies, and idiosyncrasies were very difficult to explain. He had seen prolonged systematic treatment with a vaccine of bacillus coli sometimes prove of benefit.

Mr. A. EDDOWES (London) related a case in which a man who had always been in good health developed an eruption of urticarial type after drinking a glass of ale, and also a case in which a similar result had followed taking shrimps.

Dr. LESLIE ROBERTS (Liverpool) described the classification of these skin affections, and expressed the opinion that lupus erythematosus was due to disease of the lymphatic glands.

Dr. J. H. SEQUEIRA (London) distinguished clearly between the chronic and acute forms of lupus erythematosus.

The PRESIDENT of the Section related a case of acute lupus erythematosus in which no cause could be found, and there was no suspicion of an excess of alcohol. The patient remained under observation for a year, and it was afterwards discovered that she was an alcoholic. He had seen some cases which were associated with endocarditis.

DISEASES OF CHILDREN.

WEDNESDAY, JULY 26TH.

President, Dr. OTTO J. KAUFFMANN (Birmingham).

The PRESIDENT having opened the business of the Section with a few introductory remarks,

Dr. H. D. ROLLESTON (London) read a paper on the

Diagnosis, Prognosis, and Treatment of Tuberculous Peritonitis.

He said that tuberculous peritonitis had been divided into:—1. Acute Forms: (*a*) miliary form, part of generalised tuberculosis with abdominal pain, vomiting, and tympanites; (*b*) miliary tuberculosis of the peritoneum and pleuræ; and (*c*) miliary tuberculosis around the cæcum resembling appendicitis. 2. Chronic Forms: (*a*) ascitic; (*b*) caseous, ulcerating, or suppurative; (*c*) fibrous; and (*d*) localised. He said that diagnosis was most difficult in the earliest stages. The disease was sometimes latent, and only discovered at an operation performed for a hernia, which was often the first evidence of tuberculosis of the peritoneum, as it was forced out by the increased abdominal pressure due to ascites. The diagnosis was most difficult in young babies, a distended abdomen being comparatively common as the result of gastro-intestinal catarrh. The onset appeared to be acute in about a third of all the cases, and might at first strongly suggest appendicitis. In acute cases due to generalised tuberculosis the aspect might closely resemble enteric fever. Acute cases might also be readily confused with pneumococcic peritonitis. Ascites in children was so generally due to tuberculous peritonitis that its presence was highly suggestive of that condition. Hepatic cirrhosis being so rare in children cases of that disease were occasionally mistaken for tuberculous peritonitis. Other conditions causing ascites in children were late hereditary syphilis, obliteration of the hepatic veins (very rare), simple chronic inflammation of the peritoneum, malignant disease of the peritoneum or mesenteric glands. The prognosis of tuberculous peritonitis was, generally speaking, better in children than in adults. The prognosis was better in ascitic and fibrous cases than in caseous and ulcerative cases, and as a rule the more acute the onset the worse the prognosis. The presence of active tuberculosis elsewhere made the outlook grave, and the prognosis was also bad in mixed infections, shown by a continued temperature, night sweats, and definite leucocytosis. Treatment was considered

under the following heads: I. Hygienic Treatment. Absolute rest in bed, as far as possible in the fresh air and in the sun. Margate was specially recommended. II. Medicinal Treatment. Not so important. Iodine was used in the forms of iodoform, syrup of iodide of iron, and hypodermic injections of iodine with iodide of potassium and guaiacol. Salicylate of bismuth or salol might be tried, and opium for obstinate diarrhœa. Locally mercurial ointment rubbed into the abdomen by a bandage might be tried, and iodine or iodoform might be used in the same way. The action of the bandage, besides assisting absorption of the drugs, was important in securing rest to the abdomen. The diet should be nourishing and largely proteid, with the addition of cream and fatty food, including cod-liver oil. Starchy and vegetable food should be avoided, as liable to cause flatulence. III., Vaccine Treatment. There was much difference of opinion as to its efficacy. Wright and Latham recommended it, but Still found it of no effect, and his (Dr. Rolleston's) experience of it was doubtful. IV., X rays had been given a fair trial, but did not appear to be of any real therapeutic value. V., Surgical Treatment. Operation was contra-indicated in general or widespread tuberculosis, in infants under 12 months of age, and in patients with signs of pulmonary tuberculosis. It was unnecessary in the fibrous and adhesive forms, in the absence of any urgent symptoms of intestinal obstruction, and it was necessary in cases of abscess formation and in intestinal obstruction. It had been supposed that operation reduced the feeble vitality of the peritoneal tubercles so that they underwent death and involution. More recently the explanation was put forward that peritoneal tuberculosis being a local infection the opsonic index of the ascitic effusion was lower than that of the blood; hence after removal of the ascites there occurred a fresh effusion which was of a higher opsonic index, and therefore had a curative effect on the local tuberculous process. If this was true, simple paracentesis should be as effective as laparotomy, but the advantage of laparotomy was that a local focus of tuberculosis which might give rise to reinfection and relapse after partial or apparent cure might be thus detected and removed. It was generally agreed that the ascitic cases did well whether operated on or left alone, but as some cases began as ascites and went on to ulcerative stages, early laparotomy might prevent these sequels. Statistics on these points would be of value.

Professor G. A. WRIGHT (Manchester) said that pneumococcic peritonitis appeared to be rare in Manchester. It might be very difficult, without bacteriological examination, to distinguish it from the tuberculous disease. In his experience an acute, severe, generalised peritonitis without definite local cause, accompanied by rapid and great distension, great pain and tenderness with high fever and diarrhœa, and usually ending fatally, was probably pneumococcic. A localised abscess might be due to a breaking-down tuberculous gland, or to typhoid or appendicitis, or might be pneumococcal. The round, tense, distended, shiny abdomen, with full veins, fluid in the flanks and possibly localised collections elsewhere, with resonance round a protruding umbilicus, and all these conditions without pain, tenderness, or fever, was in all probability tuberculous. The diagnosis was still more certain if localised hard masses could be felt. The three most constant conditions were distension, pain, and the presence of a local palpable mass. Elevation of temperature appeared to exist in only a small minority of cases. The diagnosis might be very difficult and only to be certainly made by operation. As to the ultimate results of laparotomy and its value as a means of treatment, he summed up as follows: 1. That probably not much more than half the cases would live to grow up, for of those who recovered for a time a large proportion died from tuberculosis in some form within a few years, though the immediate operative mortality was small. 2. There was no hard-and-fast line between ascitic and plastic cases either as a matter of morbid anatomy or of operative treatment or of mortality. But operation was simple when there was much fluid and might be impossible in obliterative cases. 3. Tuberculous mesenteric glands might be safely removed and in some cases certainly should be removed.

Dr. C. H. MELLAND (Manchester) said that he formerly used to call in the aid of a surgical colleague in these cases, but that he had latterly relied more on medical treatment, diet, hygienic influences, and the use of Scott's dressing or a bandage to the abdomen, with equally satisfactory results.

Mr. W. MCADAM ECCLES (London) said that there were at least five reasons why the surgeon was inclined to advise operation in these cases: 1. Incision was safe, far safer than mere paracentesis. 2. Exposure of the peritoneum confirmed diagnosis. 3. Laparotomy might, and frequently did, expose a removeable tuberculous focus. 4. Opening the abdomen would allow of the wider application of remediable substances. 5. Operation necessitated subsequent rest with the abdomen firmly bandaged.

Mr. GEORGE HEATON (Birmingham) divided cases of tuberculous peritonitis into three main classes from the surgical point of view: 1. The fibrous adhesive forms, which should not be operated on. 2. Ulcerous forms. Here active surgery was contra-indicated, or should be limited to the opening of any localised abscesses which might form. 3. The ascitic variety, in which laparotomy was indicated.

The PRESIDENT illustrated one of the difficulties of diagnosing tuberculous peritonitis by exhibiting a specimen of extensive subserous sarcoma of the peritoneum which had been mistaken for tubercle. In his opinion the per cutem administration of mercury ointment was the most valuable therapeutic agent, and he drew attention to its effect in slightly diminishing the number of leucocytes.

Dr. W. E. HUME (Newcastle-upon-Tyne) read a paper on

General Œdema Following Gastro-enteritis in Children,

based on 13 cases he had observed in infants free from cardiac or renal disease. The treatment employed was the subcutaneous injection of adrenalin chloride solution, and was successful. He thought the condition might have been due to fibrosis of the suprarenal glands.

Dr. ROLLESTON said he had seen such cases, and that, though rare, when they did occur they did so in small groups. Presumably the condition was toxic. Possibly œdema of a similar kind in the kidneys might induce albuminuria. So some cases of general œdema with albuminuria might be of this nature and not primarily renal.

Dr. R. H. MILLER (London) asked if the medullary changes were not found in the suprarenal glands of marasmic children dying without œdema.

Dr. ANN ELIZABETH CLARK (Birmingham) said that cases of general œdema in children under three years of age were not rare, and in her experience recovery was usual.

The PRESIDENT thought that these cases would be observed in greater numbers when attention had been called to them, as by Dr. Hume's remarks. In his opinion the morbid phenomena might be due to a vaso-motor paralysis, produced by a toxic material of intestinal origin. The good effect of suprarenal extract might be the direct result of increasing the blood pressure, which was so extremely low when the patients first came under observation.

Dr. HUME briefly replied.

Dr. LEONARD G. PARSONS (Birmingham) read a paper on

Infantilism Associated with Chronic Interstitial Nephritis.

Its purpose was, he said, to direct attention to a class of case which had apparently escaped general recognition. He could only find one case described in the literature—a living patient shown by Dr. H. Morley Fletcher at the meeting of the Section for the Study of Disease in Children of the Royal Society of Medicine last March. Infantilism strictly meant the non-appearance at the proper time of the primary sexual characteristics or of the associated secondary sexual characteristics, but the term was frequently applied to children who were backward in bodily development. Dr. Parsons's case was a girl aged 6½ years, who had been suffering from wasting and excessive thirst. In bodily and mental development she was like a child of three years old. There was œdema of the legs and face and some evidence of broncho-pneumonia. The urine was pale in colour, acid, specific gravity 1010, and showed a faint trace of albumin, but no casts, sugar, or cells. Death occurred on the seventh day after admission. Post mortem the kidneys were found extremely small, and together weighed less than an ounce. Miscroscopically there was a most extensive general fibrosis of cortex and medulla, more marked than ever obtained in the most advanced cases in adults. Speculation on the cause of this condition of infantilism was fascinating. Bradford had shown that removal of two-thirds the weight of the kidneys in animals produced polyuria and wasting. He was inclined to attribute his results to the diminution of an internal secretion of the kidneys. This would put infantilism associated with granular kidney on all fours with cretinism. On the other

hand, the condition might be due to the presence of a chronic disease which hindered the proper carrying out of the functions of the body.

Dr. JAMES E. H. SAWYER (Birmingham) said that he had published 55 cases of chronic interstitial nephritis. In none of these had he found infantilism, meaning mental backwardness, but in most of the cases there was great backwardness in growth.

Dr. ROLLESTON considered that the easiest explanation of Dr. Parsons's case was that both the infantilism and the renal changes were due to congenital syphilis.

After some remarks from Dr. MILLER and the PRESIDENT, and a brief reply from Dr. PARSONS, the business of the session closed.

ELECTRICITY AND RADIOLOGY.

WEDNESDAY, JULY 26TH.

President, Dr. HUGH WALSHAM (London).

The proceedings in this Section were opened by a short address from the chair by the PRESIDENT, who drew attention to the progress made in medical electricity and radiology during the last 25 years, and made special reference to the work done in St. Bartholomew's Hospital, first by the late Dr. W. E. Steavenson and secondly by his successor, Dr. Henry Lewis Jones. It was specially noteworthy that though a section on these subjects was refused by the British Medical Association for many years it seemed that now it had become as much a part of the regular programme as any other. This was cause for great satisfaction; it should act as a stimulus to their work, if any were needed, and would do much to improve the position of medical electricity and radiology in the eyes of the profession and the public alike.

Professor Sir OLIVER LODGE (Birmingham) gave an address

On the Conveyance of Electricity through Solids, Liquids, and Gases.

This interesting and important subject was treated from the point of view of the most modern theories. The transfer of electricity is by means of electrons carrying definite negative electrical charges, and in a metal these carriers or ions flow through it, because the electrons composing the metal are moveable. Thus the transference in a solid is *through* matter, with a rapidity comparable to that of ordinary light—i.e., about 1/20th of the speed of light. In the case of liquids, the electrolyte is made up of groups of ions in which the electrical charges are exactly balanced. The current being turned on, there is a shifting of the ions owing to the extra electrical charges to be transmitted, the positive ions moving with the current and the negative ions against the current. Both positive and negative ions take part in the transference, which in this case takes place *with* matter. Coming to the consideration of the conveyance of electricity through gases, it is found that it takes place mainly through the agency of positive electrons. These travel very slowly—about 1/20,000th of the speed of light; but because they are very numerous they carry most of the current, and also they travel *free of matter*. Radiation is explained as being due to the acceleration of the electron, which acceleration may be positive or negative, and merely altered in direction. An electron, suddenly hurried on, retarded or made to describe a curve, technically undergoes acceleration, and radiation is a result. In an ordinary lamp filament electrons are rushing about with great rapidity—i.e., are in a state of constant acceleration. The X ray is a result of suddenly stopping an electron or group of electrons, giving rise to solitary impulses—the "whip-crack" of radiation. This very interesting and instructive address was brought to a close by a description and demonstration of the action of a form of valve tube invented by himself which possesses a high efficiency, and by its assistance a more or less permanent charge could be given to a Leyden jar.

Dr. H. LEWIS JONES (London) opened a discussion on

Ionic Medication and the Theory of Ions

by saying that Stephane Leduc had done a great deal to clarify the ideas of medical electricity by his writings upon the rôle of ions in medical work. He had taught them how to apply large currents with a minimum of discomfort, and how to approach the treatment of a number of morbid conditions by electrical methods. The shock of the induction coil current, the sting of the continuous current, and the painlessness of high-frequency currents were all functions of ionic movement. The latter, by the rapidity of its oscillations, produced insufficient movement of ions to disturb the chemical equilibrium of the nerve and muscle, and therefore caused no shock or pain unless it were very highly concentrated. Dr. Lewis Jones considered that evidence was still needed as to the penetration of ions, not so much whether they penetrated or not as whether they could be made to penetrate far enough for practical purposes, as, for instance, in the treatment of joint affections. Perhaps the observed good results depended upon the commotion of the natural ions of the tissues rather than upon the introduction of extraneous ions from without. He referred to the useful results of ionic medication in facial neuralgia, and suggested that facial paralysis should also be treated by ionic applications to the trunk and main branches of the nerve, and considered that he had seen good results follow this mode of treating facial paralysis. He hoped to hear the personal experiences of individual workers and considered that ionic medication was likely to render useful help to almost every branch of practical surgery and medicine. At the close of his remarks a demonstration was given of the rapid transference of ions through several thicknesses of moistened parchment paper.

A very free and full discussion followed, in which all of those who took part paid a high tribute to the excellent work on the subject that had been done by Dr. Lewis Jones.

Professor WERTHEIM SALOMONSON (Amsterdam) asked if it were possible to determine how much of an alkaloid were introduced into the tissues under any given set of conditions, and if any work had been done in the use of the poisonous alkaloids introduced in this way.

Dr. REGINALD PRATT (Leicester) spoke of the good results he had had in cases of chronic mastitis and chronic cystitis by the introduction of zinc ions. The latter was treated by means of a special form of zinc rectal electrode arranged for easy introduction and protection of the muco-cutaneous margin, which was very sensitive to electrical currents.

Dr. R. W. MCKENNA (Liverpool) bore testimony to the great value of ionisation in dermatology and he described a method suggested by his partner, Dr. G. G. Stopford-Taylor, for increasing the action of the zinc ionisation. This was to wipe over the nodules with liq. potassæ, which had the effect of rapidly dissolving off the gelatinous covering. After washing with saline solution or distilled water the ionisation was commenced and continued for about 20 minutes. This was repeated after 14 days if necessary. He claimed a result superior to that of any other method, not excepting that of Finsen.

Dr. J. METCALFE (Bradford) also found ionisation of great value in superficial disorders.

Dr. L. W. BATHURST (London) said that, as the result of some experience of ionisation, there were some points which he should like to emphasise. With regard to the all-important matter of technique, he had followed closely the methods of Leduc, using pads equal to not less than 16 thicknesses of lint thoroughly saturated with the solution employed. He had tried many forms of electrode, but knew of none better than a particular gilt wire gauze with fine meshes sold for the trimming of ladies' hats under the trade name of tricotine. Another excellent electrode was a pot-cleaner made of strands of copper-wire. Before using these he had employed thin metallic sheets which could be bent and moulded, but much less perfectly, to the shape of the part. Dr. Bathurst regarded the strength of current as being of great importance, relatively strong currents being, he thought, essential. But this must vary in accordance with: (1) The size of the electrodes; (2) the region of the body under treatment; (3) the sensitiveness of the patient to pain; (4) the reaction of the individual's skin, for skins seemed to vary very much in their reaction to ionisation; and (5) the ions employed. Much stronger currents, for example, could be used with salicylic ions than many others. As a rough index of the current he was accustomed to employ, he should consider in the treatment of a large joint, such as a knee, a current of 30–40 ma. as a minimum, 50–70 ma. as average, and 100–150 ma. as exceptionally strong. In his case the current was induced gradually, as much as a quarter of an hour being occupied in attaining a maximum. In this connexion he wished to speak particularly of the reaction of the skin, which might be only a slight redness or might amount to destruction of tissue. This reaction was in

accordance with the factors just noted and with the strength of the current. The important points for the avoidance of burns were thickness of pads, and even pressure of the electrodes. It was for this reason he gave up the solid sheets of metal in favour of those which could be evenly applied and held in position by a bandage. Caution as to the strength of current must be had in each case, for he had known burns to occur with currents of even 20 ma., especially if any abrasion of the skin be present. It was well in these cases to cover such abrasion with a small piece of some non-conductor. The duration of treatment had been from 10–30 minutes and in hospital cases twice a week; but experience led him to think that more frequent treatment was of great advantage. The strength of his solutions had been 1 per cent. throughout. Those mostly used were: (1) Sodium chloride for chlorine ions; (2) sodium salicylate for salicylic ions; (3) zinc chloride for zinc ions; and (4) potassium or lithium iodide for iodine. Chlorine ions had been used chiefly for joints stiffened with fibrous thickening, superficial scars, and keloid growths. The most satisfactory results had been shown in this class of case. A stiff and painful shoulder-joint coming on after childbirth, which had resisted the action of drugs given by the mouth and massage, cleared up completely under chlorine ionisation. An extensive scar of the face with keloid growth showed very great improvement with six weeks' treatment; and a hand from which a supernumerary finger had been removed, and in which the adjoining fingers were useless owing to a large amount of scar tissue, regained complete use of the fingers by chlorine ionisation. Salicylic ions had been used chiefly in (*a*) rheumatic affections of joints and rheumatoid arthritis, and (*b*) in various forms of neuralgia and neuritis. In the joint affections great relief was generally experienced, and where no active infection was present marked improvement of the physical signs could be noted. In neuralgias where no auto-intoxication was in progress great improvement might be noted. A man who for 20 years had had trigeminal neuralgia said after his second treatment that he had known no such relief in that time. In an elderly lady with the same affection, which had been getting progressively worse, so that morphine injections had been resorted to at frequent intervals, two such injections only had been necessary in seven months since ionisation was commenced. The spasms of tic douloureux also had been seen to disappear after three or four applications. Zinc ions Dr. Bathurst had used chiefly for chronic ulcers and sinuses. A large ulcer of the heel following thrombosis of the leg after parturition had left a woman of 25 bedridden in spite of excision of the ulcer and treatment as an in-patient. She had not put her foot to the ground for eight months when zinc ionisation (20 ma. for 15 minutes) was applied to the ulcer, which was about the size of a crown-piece. This treatment was repeated a week later, and the ulcer was completely healed in three weeks. These and other results had encouraged him very much in the treatment by ionisation, the more so when he considered the unpromising cases which formed the bulk of his hospital patients. But he thought the relief given in the most distressing forms of neuralgia, the effect on scar tissue, especially if near the surface, and the almost magical effect on chronic ulcers and sinuses more than justified the plea for an extension of this form of treatment.

Dr. N. S. FINZI (London) made an interesting statement as to how one could tell if any particular ion was penetrating deeply. If an ion was not one to penetrate deeply it was usually because it accumulated near the surface, forming compounds with the constituents of the tissues, and these formed a barrier and thus increased the electrical resistance. Thus, if the milliampèremeter be watched the hand at first slowly rose, stopped, and then receded. If it was a deeply penetrating ion the hand of the instrument slowly rose, and later might become stationary, but did not recede.

Dr. A. H. PIRIE (London), Dr. J. DELPRATT HARRIS (Exeter), Dr. C. F. BAILEY (Brighton), Dr. E. REGINALD MORTON (London), and Dr. MAURICE R. J. HAYES (Dublin) also took part in the discussion.

In his reply Dr. JONES stated that they were not yet in possession of any reliable means of determining the actual amount of any ion introduced in this way. In the treatment of rodent ulcers he admitted that he always selected his cases, as the method was not reliable in those old-standing cases where it was extending more or less deeply, but in suitable cases the results were all that could be desired. With regard to the use of strong solutions for ionisation, 10 per cent. or more, he could not see how these could be of any real advantage, as there were far more ions present in the usual 2 per cent. solution than could possibly be made use of in any ordinary application.

Dr. BAILEY read a paper entitled

Fractures Undiagnosable except by X Ray Examination.

He showed how an X ray examination removed all doubt as to the existence or non-existence of a fracture in a large number of doubtful cases, and also revealed the existence of fractures in structures not previously described, such as that of a transverse process of a lumbar vertebra from muscular action. The paper also went on to show that there were very few cases of more or less severe injury where it was advisable in the interests of both patient and doctor to omit a proper X ray examination. In this most radiographers of extensive experience will heartily agree, for however skilful may be the clinician errors of diagnosis are bound to occur, and an X ray examination provides an invaluable safeguard. In doing this it was very properly pointed out that we never should be satisfied with a screen examination, as fractures without displacement were very seldom detected in this way, and in all cases a stereoscopic radiograph would add sufficient to our knowledge to make it well worth the trouble of doing. These points were well demonstrated in the radiographs with which the paper was illustrated, especially in cases of injury about the wrist.

Dr. J. A. CODD (Wolverhampton) gave instances of cases where fractures were only discoverable by X-ray examination.

Dr. PIRIE drew attention to the fact that while the stereoscopic method was the best for some parts of the body, in others, such as the ankle-joint, an antero-posterior and lateral view gave the most valuable information.

Mr. F. EMRYS-JONES (Birmingham) and Mr. J. HALL-EDWARDS (Birmingham) stated that the X ray method of examination had led to superior results in treatment.

Dr. MORTON, while wishing to discourage anything in the nature of slackness in making a clinical examination, said that in these days a high standard of perfection was demanded, and referred to the Workmen's Compensation Act and other circumstances. He considered that every case of fracture ought to be radiographed—the screen was not accurate enough—and it would be found that in every case it would add something to their knowledge of the case, which could never be too great, in the interests of the patient. He thought that the medical man who treated fractures without X ray examination in these days, especially if in the vicinity of a joint, was going out of his way to seek trouble, and that he must not be surprised if he found it.

Dr. J. METCALFE (Bradford), Dr. HAYES, and Dr. HARRIS all bore testimony to the facts brought out by the reader of the paper, and Dr. BAILEY replied.

Finally, Dr. PIRIE showed a new form of Stereoscope.

LARYNGOLOGY, RHINOLOGY, AND OTOLOGY.

WEDNESDAY, JULY 26TH.

President, Mr. FRANK MARSH (Birmingham).

The PRESIDENT, in a brief address, after welcoming the visitors from over the seas, mentioned that Birmingham possessed one of the oldest established hospitals in the kingdom for the special treatment of diseases of the throat, nose, and ear. It was established 70 years ago and contained 41 beds for the treatment of in-patients. Unfortunately there was no chair or provision for teaching these special subjects in the University. That might be due to there being no predominance of these diseases in Birmingham, partly owing to the high sea-level, and partly to the absence of any industry especially conducive to their development. Referring to the Insurance Bill, specialists, he said, probably would not be much affected. The State might have to subsidise special hospitals which might come under State or municipal control. If so, provision would have to be made for the medical staffs on the hospitals, and a representative committee of hospital staffs in that case should be formed. The triology of laryngology, otology, and rhinology being united again in one section he thought

was satisfactory; if separated then rhinology might prove itself to be the predominant partner. He referred to the Oxford diploma in ophthalmology. Specialists in their own triology possibly might one day adopt a similar course in view of the inadequate teaching of the subjects in the universities. There was, however, the danger of such a diploma in future being granted to persons without a sufficiently high standard of knowledge of general medicine and surgery.

Dr. J. DUNDAS GRANT (London) and Dr. P. WATSON-WILLIAMS (Bristol) opened a discussion on the

Treatment of Laryngeal Tuberculosis.

Dr. DUNDAS GRANT confined himself mainly to the consideration of various local etiological factors and methods of treatment. Amongst the causes of localisation of the disease in the larynx he mentioned irritants, including under these excessive use and abuse of the voice, urging maintenance of silence for three or four months. Marked improvement followed even whispering if a genuine whisper were adopted. Useless injurious coughing should be controlled, and if possible a voiceless cough should be acquired. Tobacco smoke and irritating vapours were also factors. Nasal obstruction and nasal discharges were predisposing causes. Therapeutic measures were to be founded on the treatment of these irritants. Continuous antiseptic inhalations acted beneficially by checking cough. The removal of nasal obstruction and pathological secretions from the nasal cavities was important and yielded good results upon the laryngeal disease. He spoke of the beneficial results following upon the use of the galvano-cautery puncture. For the relief of important symptoms, such as severe dysphagia, local sedatives administered in the form of powder by means of a tube were advised. If the dysphagia were extreme recourse might be had to alcoholic injections into the superior laryngeal nerve. The regurgitation of liquids might be overcome by Wolfenden's method, or by the use of a feeding tube whilst the patient was lying on the back on the floor. In advising and carrying out local treatment regard and caution had to be paid to the patient's general condition and temperament.

Dr. WATSON-WILLIAMS considered, although there had been several discussions held on the subject within recent years, that the last word had not been said. Reference to the pathogenesis of tuberculous affections of the larynx, and the differentiation of clinical varieties afforded prognostic importance from the therapeutic standpoint. Sanatorium treatment alone without local treatment at times yielded remarkable results and a lasting recovery. Regulated exercise and rest of the voice were amongst the factors in the recoveries obtained through sanatorium treatment. A dry climate and a high altitude had no beneficial influence on the larynx. Nasal obstruction should be treated. Tuberculin treatment was useful in certain cases. He had known tuberculin relieve a patient's sufferings for a remaining eight days of life. Fibroid granulations and tuberculomata in the interarytenoid region and along the ventricular bands might be removed if producing aphonia, and the condition of the lungs permitted of such surgical treatment. Dr. Watson-Williams demonstrated a series of lantern slides illustrating the points he had dealt with.

Mr. G. SECCOMBE HETT (London) exhibited and demonstrated a collection of specimens of parts removed from cases of laryngeal tuberculosis. In a series of 30 cases he had amputated the epiglottis in 24, and the collection included 12 of these and part of the arytenoid region from another case. Relief had been immediately afforded. He advised some traction being put upon the epiglottis to ensure it being amputated down to the stump, as he had found when this had not been done it had been necessary subsequently to remove a further portion.

Dr. W. JOBSON HORNE (London) based his views of the surgical treatment of laryngeal tuberculosis upon his investigations into the pathogenesis of the disease. He summarised his conclusions as follows: 1. That when the larynx is infected with tubercle the disease is already established in the lung. Primary tuberculosis of the larynx is a negligible quantity. 2. That the disease in the larynx progresses *pari passu* with that in the lungs; when the disease in the larynx presents ulceration that in the lungs has advanced to cavitation; and *vice versâ*, when that in the lungs has become arrested, then that in the larynx heals. 3. That when the disease in the lung is confined to the pure miliary form the larynx is not infected. 4. That infection of the larynx takes place by the sputum from the lungs through the opening of the ducts in the laryngeal mucosa. 5. That the regions of the larynx more prolific with glandular structure are more vulnerable to tuberculosis. 6. That the regions of the larynx covered with columnar-cell epithelium are more prolific with glandular structure, and therefore are more vulnerable to the disease than the parts covered with squamous epithelium. Hence, the central part of the vocal cord itself becomes involved only by continuity of the disease and offers the greatest resisting powers. 7. That the rational treatment is to preserve the mucous membrane covering the larynx and to induce a metaplasia of the columnar mucosa into the squamous variety. That is to induce the condition of pachydermia laryngis. This is the natural process of arrest of the disease. The natural process of arrest can be induced and imitated by absolute rest of voice and the submucous puncture with the galvano-cautery point. These conclusions were based upon a series of specimens; photographs of many were exhibited in the loan museum formed in connexion with the meeting, and were fully described in the catalogue. Dr. Jobson Horne urged the routine and the early examination of the larynx in all cases, and especially doubtful cases of phthisis even when there were no pulmonary signs. Thereby extreme surgical measures could be avoided.

Dr. E. F. TREVELYAN (Leeds) agreed that patients should be taught how to cough. He did not agree with continuous antiseptic inhalations except in cases of bronchitis. He had not seen good results from tuberculin; those who got such a high percentage of recoveries must get different material to work upon. Patients with dysphagia could bolt eggs.

Dr. S. MORITZ (Manchester) spoke from his experience at a hospital that was exceptional, inasmuch as it existed for the combined purposes of treating consumption and diseases of the throat. He regarded the unbroken mucous membrane of a larynx infiltrated with tubercle as a *noli me tangere*. The general condition of the patient must be good to permit of the removal of parts of the larynx by surgical measures. Surgical treatment was liable to cause a small ulcer to become a larger one.

Dr. ANDREW WYLIE (London) was in favour of a masterly inactivity in the treatment of laryngeal tuberculosis. Moist climates—open moorland—as in Cornwall, Yorkshire, or Scotland, were better than Switzerland.

Dr. DAN MCKENZIE (London) was also in favour of considerable inactivity. He advocated removal of nasal obstructions and free nasal respiration.

Dr. L. H. PEGLER (London) also supported the removal of nasal obstructions.

Dr. G. WILLIAM HILL (London), speaking generally, was opposed to operations for nasal obstructions in patients with consumption.

Dr. N. C. HARING (Manchester) was opposed to the surgical removal of parts of the larynx except in cases of circumscribed lesions; then operate for relief and not for cure. With tuberculin he had seen the larynx getting better, whilst the pulmonary lesion was getting worse—an argument against the surgical treatment of the larynx.

The PRESIDENT summed up the discussion. The Section, he concluded, was in favour of conservative methods, such as silence, intra-laryngeal injections, and the galvano-cautery puncture. Operations could be done on the nasal passages in selected cases. Tuberculin had its place, but was not much advocated. Individual conditions must be the guide to the choice of treatment.

Dr. DUNDAS GRANT and Dr. WATSON-WILLIAMS replied, and Mr. SECCOMBE HETT also briefly replied.

Dr. HILL read a paper entitled

Dysphagic Conditions Wrongly Attributed to Œsophageal Spasm.

The paper was based upon anatomical considerations as well as upon clinical observations. He maintained there was no such thing as a primary idiopathic spasm of the œsophagus in the commonly accepted sense of the term.

The PRESIDENT was also of the opinion that caution should be exercised in the use of the term idiopathic.

Dr. JOBSON HORNE agreed generally with the views expressed and cited a case in support of these views.

Dr. MCKENZIE pointed out that any irritation might set up

a spasm of the œsophagus and the spasm in turn might bring about dilatation of the œsophagus.

Dr. A. BROWN KELLY (Glasgow) inquired, if dysphagic conditions could not be attributed to œsophageal spasm, how death from starvation following dysphagia, in which post mortem no disease was found in the œsophagus, could be accounted for.

Dr. DUNDAS GRANT was not disposed to throw away altogether the theory of functional spasm. By doing so the patients might be made unhappy.

Dr. PEGLER cited the case of a lady now aged 80, who for 30 years had not been able to swallow solid food. Malignant disease after that length of time he considered should be excluded and the case regarded as one of functional spasm.

Dr. HILL replied, maintaining his original contentions.

MEDICAL SOCIOLOGY.

WEDNESDAY, JULY 26TH.

President, Dr. GEORGE REID (Stafford).

The PRESIDENT, in his opening remarks, spoke of the wide field covered by the term "medical sociology"; it was, indeed, the pivot of the whole social movement, for the nation's health was the crux of national prosperity, and with a low health standard social progress was impossible. Who, then, were better fitted to speak authoritatively on social questions than medical men? The vital factor in all national progress was public opinion; unless the people were roused and their sympathy secured, all agitation was futile. That the nation was becoming more alive to the importance of the health factor in securing and maintaining its prosperity and social welfare was shown by recent legislative enactments; for example, the Notification of Births Act, the Education (Administrative Provisions) Act, and the Housing and Town Planning Act, not to mention the National Insurance Bill now before Parliament. In this measure the legislature proposed to tamper with the interests of medical men to an extent that would practically ruin a large section of the hardest workers in the profession. Nevertheless, if reasonable amendments could be secured in the Bill, medical men should do their utmost to make invalidity insurance a success. The scheme could not be carried through without their coöperation, and unless they received fair treatment they must not hesitate to exercise their veto.

Mr. J. SMITH WHITAKER, medical secretary to the Association, opened a discussion on

The Medical Aspects of the Poor-law,

with special reference to State insurance and the provision of better medical attendance on the poorer members of the community. Mr. Smith Whitaker, in an endeavour to indicate the various parts of the problem in their relation to one another and to the broader social problems of the hour, pointed to two directions in which public opinion had been tending. One was the appreciation by the whole community of the fundamental importance of the health of each individual, and the other the greatly increasing tendency to look to the machinery of the State as the instrument for effecting social reform. They could trace the sequence of events from the Commission on the Poor-law of 1832 to the Report on Physical Deterioration. That led to the appointment of the Royal Commission on the Poor-law, which in its turn was responsible for the inception of the National Insurance Bill. Looked at from the purely economic side, individual health, or the lack of it, seriously affected national well-being. The person who could not obtain proper medical attendance was liable to become a charge on the community, and the community also suffered from the loss of his labour. Analysing the main causes of sickness they were found to be due not only to absolute lack of means to provide necessary medical attendance, but also to defective social organisation which did not enable the individual to apply such resources as he possessed to the best advantage. In this connexion Mr. Smith Whitaker condemned the too narrow definition of the word "destitution" that had been observable in the discussion of both the Majority and Minority Reports of the Royal Commission. Destitution was a relative term; it did not depend upon whether a person had money, but whether his resources were equal to satisfying the needs of the moment. A man in need of institutional treatment was destitute if no hospital was available and he could not afford an operation or a nursing home. Destitution might consist in the want of ready money, and that was where the principle of insurance against sickness came in. As to the method of dealing with the difficulty, the proposal in the Minority Report to adopt a system of charge and recovery might be dismissed as impracticable. The medical profession felt strongly—not in its own but in the public interest—that individual medical attendance would best be given on the lines of private practice, and that the employment of the whole-time officer was not a sound principle. That was the foundation of the whole of their objections to the Minority proposals and also to some of the possibilities of the Insurance Bill. Mr. Smith Whitaker concluded by re-stating in detail the medical objections to the Bill.

Dr. F. E. WYNNE (Leigh) read a paper on

The State Distrust of the Profession.

He pointed to the treatment accorded to medical men by clubs, Friendly Societies, insurance companies, and public bodies, and to such legislation as the Midwives Act and the Notification of Births Act as evidence of that distrust. The fact that the nature of the medical man's services made it ethically impossible for him to refuse them had been used to cheat the profession of its just rights, and its own jealousy and disunion had completed its serfdom. Distrust of the honesty of the profession in the prevention of malingering, and not the cost of a system of payment for work done, was responsible for the adoption of the contract system in the Insurance Bill. The aim of medical men must be to convert distrust into confidence, but before they could be trusted it appeared they must make themselves feared. The directors of great insurance companies, the judicial bench, local bodies, and Parliament were all contemptuous in their attitude towards the medical profession. What were the reasons? The public still had a degree of belief—perhaps subconsciously—in quackery, and so had a doubt as to the intrinsic value of the doctor's knowledge. Another reason for distrust was the growing spirit of coöperation and union amongst medical men. The public could see in doctors' organisation nothing but an attempt to make them pay for services they had come to believe themselves entitled to receive for nothing. Dr. Wynne urged that the present crisis afforded the profession an opportunity of insisting on new standards in its dealings with the community.

Dr. PERCY R. COOPER (Bowdon), in a communication upon

Medical Attendance under State Insurance,

criticised the Chancellor's calculations as to the cost of medical benefit and also the airy way he spoke of bringing into the scheme millions of the general practitioners' private patients. The conditions insisted upon by the medical profession were in the public interest as much as in their own. The policy of the profession was to secure modification of the Bill if possible, and, if not, to refuse to act under it. On their union and loyalty to one another the future of their great and beloved profession depended.

Mr. F. G. LAYTON (Walsall) presented an argument for

A State Medical Service.

Under the present system, if medical men were hard-headed men of business, which, thanks to the gods, they were not, they would oppose everything in the way of preventive medicine to the utmost of their power. It was notorious that they did nothing of the sort, but did all they could to keep their clients well. True, their clients frustrated their efforts, to their profit and advantage. Doctors preached the gospel of hygiene with perfect sincerity; if only people would listen the profession would be speedily ruined. With this preface, Dr. Layton went on to outline a State medical service under a Department of Public Health, the country to be mapped out into districts, and all medical men to be paid regular salaries, with numerous opportunities for promotion. Some day, when the nation had grown wise, it would meet its most insidious foe—disease—with a standing national army of health. The private venture system in this matter was out of date.

Dr. MICHAEL DEWAR (Edinburgh) discussed

The Medical Treatment of the Poor,

devoting attention to the class which, though it maintains itself as a rule, is unable to contribute towards its medical

relief. This was the class which most needed a State scheme, but the Chancellor's Bill did nothing for them. There was very small chance of any money except that subscribed by the Government standing to the credit of a man of this class in the Post Office fund. It was curious that while those able to contribute to the Post Office fund were debarred from receiving sick benefit, they were eligible for medical benefit at once. This was truly vicarious philanthropy on the part of the Government. The Government should have done more for this class and left the steady and good wage-earner alone. He believed if a plebiscite were taken the majority of the industrial classes would say they did not want to be compelled to insure against sickness because they were well able to pay for attendance. Dr. Dewar suggested that, as the present wage-limit was too high, insurers should be entitled to benefit on a contributory basis according to income. He gave reasons against the establishment of a whole-time medical service to do this work, and said private practitioners were perfectly well able to carry it out provided they received adequate remuneration.

In the following discussion,

Mr. W. HOLDER (Hull) thought enough had not been said of the benefits which the Insurance Bill would confer upon the medical man. The provisions for unemployment insurance would enable the working classes to tide over times of stress and meet their medical bills. He complained that the British Medical Association had not secured a definite minimum of remuneration to medical men in the Insurance Bill.

Mr. SMITH WHITAKER on this point explained that it was felt a minimum tended to become a maximum, and it was thought best to leave the Bill as elastic as possible in these matters so as to allow the best possible terms to be arranged locally.

Dr. J. H. KEAY (Greenwich) gave it as his experience as a medical man in a poor district that only by means of insurance could the working-classes provide for medical attendance. He regretted a lack of continuity in the Government policy in these matters. Old-age pensions had been provided on a non-contributory bases; the present scheme was contributory. He was afraid enough advantage had not been taken of the experience accumulated in Germany regarding State insurance, and that we were in danger of repeating some of their mistakes.

Dr. J. JENKINS ROBB (Bournville) declared his belief in a State medical service. He emphasised the need of taking special precautions under the Insurance Bill to prevent malingering. He also gave it as his opinion that the profession had gone too far in its opposition to the Bill and had given the impression that it was "out for fees."

Mr. JAMES NEAL (Birmingham), one of the honorary secretaries of the section, protested against this statement, declaring that the policy enunciated by the British Medical Association had been generally recognised as fair and reasonable.

NEUROLOGY AND PSYCHOLOGICAL MEDICINE.

WEDNESDAY, JULY 26TH.

President, Dr. EDWIN GOODALL (Mental Hospital, Cardiff).

The PRESIDENT opened the meeting of the section with an address on

The Possible Toxic Origin of Some Forms of Insanity,

which will be published in a future issue of THE LANCET.

Professor H. OPPENHEIM (Berlin) was then introduced to the section by the President, and received a hearty welcome. He opened a discussion on

The Different Types of Disseminated Sclerosis

by submitting a classification based on his own experience and researches. After pointing out how inadequate the classical description of the disease, as elaborated by Charcot, had long since become, Professor Oppenheim said that the disease might be classified according to the level of the central nervous system affected, in which case four main types were readily distinguishable—viz., (1) spinal; (2) cerebral; (3) cerebro-spinal; and (4) optic or ocular. I. The spinal variety of disseminated sclerosis was itself subdivisible, according as a vertical level, or an area on transverse section, was adopted for the criterion. In the former case there were (*a*) dorsal, (*b*) cervical, (*c*) lumbo-sacral and sacral, and (*d*) mixed varieties. Of these Professor Oppenheim directed special attention to the cervical type, which was characterised by pains and paræsthesiæ in the upper extremities, usually of unequal distribution, with little objective loss of sensibility, not infrequently with astereognosis and with some ataxia and some slight paresis. This last symptom might be awanting. Reference was made to certain cases under the author's own observation. In the latter case there were (*a*) the spastic type (lateral columns of the cord); (*b*) spastic-ataxic type (postero-lateral combined type); (*c*) ataxic type—so called pseudo-tabes sclerotica; (*d*) anterior poliomyelitis type; (*e*) syringomyelia type; (*f*) amyotrophic lateral sclerosis type; and (*g*) transverse myelitis type. Special attention was drawn to the importance of the (*c*) type, which in a number of ways resembled tabes dorsalis. II. Of the main cerebral type there were several sub-varieties, viz.: 1. Cerebral in the strict sense—(*a*) hemiplegic type; (*b*) pseudo-bulbar type; and (*c*) dementia sclerotica. Professor Oppenheim said that many cases of advanced disseminated sclerosis showed a varying degree of general mental enfeeblement, but actual insanity was very rare. 2. Basal type. 3. Ponto-bulbar type. 4. Cerebellar type. Instances of these were given. Their importance was considerable, for some resembled cases of encephalitis and others intracranial tumour. III. The cerebro-spinal type was the classical type of Charcot. IV. The optic or ocular type formed a class almost by itself, as ocular symptoms might be present literally for years before any other symptoms establish themselves. An instance was given where transient amaurosis and diplopia, occurring in 1895, were not followed by any systemic symptom till 1910. Objection might be made that these varying types were not so much "types" as "modes of onset," but it was a well-known fact that the disease tended to recur in sites which had previously been affected, and from the point of view of diagnosis it was important to be familiar with them all.

Dr. J. S. RISIEN RUSSELL (London) said the Section was greatly indebted to Professor Oppenheim for his masterly description of the varieties of the disease. Dr. Russell said that in his opinion, notwithstanding the multiplicity of the types, it was impossible to reduce their number. He felt that several of them were very rare in this country as far as his experience went, but he agreed on the necessity of recognising them. The pseudo-tabes variety in particular was important, but he thought the absence of definite pupil reflex changes was an aid in differential diagnosis. He asked Professor Oppenheim whether he had ever noted the Argyll Robertson pupil in pseudo-tabes sclerotica. He also remarked on the difficulty of distinguishing between disseminated myelitis and cases of disseminated sclerosis which began as a transverse myelitis type, eventually becoming typically disseminated. Dr. Russell thought it most important to recognise the cerebellar type and the spastic or spastic ataxic type, for such cases, if incorrectly diagnosed, might be needlessly operated on, inasmuch as in some ways they resembled cerebellar tumours and spinal tumours or pachymeningitis respectively.

Dr. F. E. BATTEN (London) thought some of the types so rare in his experience that he was inclined to question the advisability of describing them separately, notably the cervical type. He, too, emphasised the necessity of full knowledge of the cerebellar type, and agreed as to the readiness with which such cases might be confused with cerebellar tumours. In view of the frequency with which islets of sclerosis were found in the cortex of advanced cases, it struck him as curious that the mental symptoms were, comparatively speaking, unimportant. He had never seen insanity in disseminated sclerosis, nor had he seen a case in anyone younger than 14 years.

Professor J. J. PUTNAM (Harvard University, U.S.A.) had never seen actual dementia in disseminated sclerosis. He remarked that the types of the disease were very much the same in all parts of the world, but the frequency of the disease in different localities seemed to vary considerably. Thus it appeared to be more common in Boston than in New York.

Professor E. BONDURANT (University of Alabama, U.S.A.) referred to the difficulty occasionally experienced in diagnosing between disseminated sclerosis and general paralysis.

Dr. JUDSON S. BURY (Manchester) said the spinal type of spastic paresis was pre-eminently the type found in the

Manchester district. In uncomplicated spastic cases occurring in the adult the possibility of disseminated sclerosis was always to be considered. The spasticity was in advance of the paresis. The chief, and in fact the only, muscular group affected—and perhaps only very slightly—was the flexors of the hip. This fact was useful in differential diagnosis. He referred to a remarkable case in which the symptoms of disseminated sclerosis, which had been well marked, disappeared after an attack of small-pox.

Dr. R. T. WILLIAMSON (Manchester) also referred to the frequency of the spastic paresis type, in which he had found, as a rule, that while most varieties of sensibility were intact, pallæsthesia, or the vibration sense, was often considerably impaired in the lower extremities.

Mr. W. J. MIDELTON (Bournemouth) and Dr. DAVID BLAIR (Lancaster County Asylum) continued the discussion.

Dr. F. W. MOTT (London) said that in 2000 necropsies on patients suffering from mental disease he had found only one case of disseminated sclerosis.

Dr. E. HOBHOUSE (Brighton) also spoke.

The PRESIDENT said that in 21 years' continuous asylum experience he had never seen a single case.

Professor OPPENHEIM, in his reply, said that the rarity of any given type was no reason for omitting it from the classification. He felt that the diagnostician and clinician ought to be familiar with the different types, and all were equally important.

OBSTETRICS AND GYNÆCOLOGY.

WEDNESDAY, JULY 26TH.

President, Professor EDWARD MALINS (Birmingham).

The PRESIDENT, in opening the proceedings, said that in the department which the Section represented progress had been well maintained during the course of the past year. Much had been done in various directions, and more especially in seeking to lessen the mortality of childbirth and to diminish the amount of illness attendant upon it. It had been stated that in the special departments for diseases of women at least one-third of all cases were supplied by puerperal morbidity, and he urged the profession to consider the seriousness of such an indictment and to use all its powers to prevent such evils. The President then referred to the importance of the Midwives Act of 1902 and the great value of the Bill to the community. At the present time 31,625 names are on the Midwives Roll, of which 10,108 have passed the required examination, and another 10,000 hold certificates from other licensing bodies. Such women have all been taught the importance of rigid asepsis and the intelligent observation of the thermometer and pulse. Attention was then drawn to the difference in mortality and morbidity between the results of hospital and of private practice, and inasmuch as the health of the women of a country was one of the chief assets of that country, the President observed that he was to some extent in favour of State-aided institutions. He mentioned the case of St. Petersburg, which is equipped with 15 municipal maternity homes. In that city, in the year 1909, 19,000 cases were admitted to the hospitals with only a fractional percentage mortality. In fact, 41·9 per cent. of all maternity cases in St. Petersburg are conducted in the municipal clinics. The President paid a high tribute to the work of Sir James Simpson, whose centenary had only recently been celebrated.

Dr. C. HUBERT ROBERTS (London) read a paper on

Eclampsia occurring in Labour in a Girl aged 12; Recovery of Mother and Child.

Dr. Roberts gave a complete clinical account of a case of eclampsia occurring in a Jewess, aged 12, admitted to Queen Charlotte's Hospital on April 2nd, 1911, in labour at the end of the ninth month of her pregnancy. The girl was of medium height and weighed 8 st. 9 lb. Her pelvic measurements were as follows: interspinous, 9¼ in.; intercristal, 10¼ in.; external conjugate, 6¾ in. Considerable œdema of both lower extremities was present, but œdema of the face, arms, &c., was absent. A purulent vaginal discharge was present. The urine showed a large quantity of albumin (two-thirds on boiling). On admission the patient was in a very excitable and uncontrollable condition, and in the afternoon of the day following admission a typical eclamptic convulsion occurred. The child presented in the left occipito-posterior position and the membranes had not ruptured. Treatment was instituted by rectal salines, morphine injections, and hot packs. Labour was prolonged, but eventually rotation occurred and delivery was effected by forceps in the left occipito-anterior position. About 18 ounces of blood were lost during delivery of the placenta. The labour occupied in all 69¼ hours. Shortly after delivery a very severe eclamptic convulsion occurred. Other typical eclamptic seizures followed and the patient passed into a condition of deep coma with a rapid, feeble pulse. Gastric lavage with a solution of sodium bicarbonate was performed and castor oil (2 oz.) was introduced into the stomach. The condition became aggravated in spite of all treatment until April 6th, when the patient was conscious for the first time. Convalescence from this moment was steady and maintained, and on April 18th the urine exhibited only the faintest trace of albumin. The temperature at the height of the attack showed pyrexia of 105° F. The patient left the hospital on the twenty-eighth day in good health, with a fine healthy baby. Dr. Roberts drew attention to the rarity of eclampsia at this early age and to the seriousness of the condition. As far as mere labour in very young subjects was concerned, he thought that the cases usually ended well and that the children, as a rule, were well developed. As regards treatment, he relied chiefly upon purgatives, the use of chloroform narcosis, and saline infusion following venesection. He also had considerable faith in early lavage of the stomach, high slow rectal salines, and the employment of glucose enemata. Morphine and hyoscine subcutaneous injections were useful to check the convulsions, but should not be used if the urine was diminished in quantity. He did not think that the question of induction of labour was an important one, as most cases were met with at the onset of labour itself. Should it be necessary, he advocated the use of Hegar's dilators and the de Ribes bag, and did not think that Cæsarean section should be practised. He noted that the mortality of Cæsarean section for this condition is as much as 55–58·9 per cent.

Dr. THOMAS WILSON (Birmingham) thought that in cases of eclampsia there was at present a large element of luck as to the ultimate result. The cases that at first appeared mild often developed serious complications and the patients died, whilst not infrequently women *in extremis* would suddenly recover. He further asked why the prognosis should vary in different countries or parts of a country. At the Birmingham Maternity Hospital the mortality over several years registered 33 per cent., whilst Stroganoff at St. Petersburg quoted a mortality of 5 per cent. over a series of 200 cases. Does this mean that the treatment at St. Petersburg is more efficacious, or that the disease there falls under a different category? As regards treatment he certainly thought that induction of labour should be considered, and for the spasms he relied upon chloroform and morphine. He thought that the urine was of little value in prognosis unless absolute suppression was present, and he considered that an examination of the urine during the later months of pregnancy had no great value in foretelling the incidence of eclamptic convulsions.

Dr. HERBERT R. SPENCER (London) was in agreement with the views expressed by Dr. Wilson as to the difficulty in prognosis with eclampsia. His first 13 cases had all recovered, but this success was marred by later cases, which had not terminated so happily. He referred to the presence of abdominal pain associated with œdema of the extremities as of some value in foretelling the incidence of convulsions. As regards treatment, he somewhat doubted the efficacy of infusions.

Dr. J. B. HELLIER (Leeds) now advocated a purely expectant method of treatment and deprecated resort to such means as abdominal section and dilatation by Bossi's instrument. He referred to the risks of repeated pregnancies in eclamptic patients, but a study of statistics had shown him that these risks were not always as bad as they had been stated.

Dr. JOHN CAMPBELL (Belfast) said that when convulsions were present he always administered morphine, ruptured the membranes if labour had not commenced, and then conducted a purely expectant method of treatment. He thought that examination of the urine during the later months of pregnancy was a distinct asset in foretelling the onset of eclampsia. So many women suffer from transient œdema of the extremities in the later months of pregnancy

that unless albuminuria is present as well, little faith can be placed upon the former.

Professor PAUL STRASSMANN (Berlin) referred to the frequency of vaginal Cæsarean section in Germany in the treatment of eclampsia. He cited especially the work of Bumm and Krönig. The latter also practises renal decapsulation. As an explanation of the varying results obtained in eclamptic patients, he suggested that seasonal conditions may have a distinct bearing. Certainly in Berlin the mortality and incidence varied at different periods of the year. Cases were more frequent in March and April, and coincided with the incidence of bronchitic and other similar affections. He thought that the kidneys may be more susceptible to the toxins at these periods. He could offer no suggestions as to the ultimate prognosis in any given case of eclampsia.

Dr. R. C. BUIST (Dundee) emphasised the importance of employing the results of large clinics in estimating the value of any particular treatment. He had seen good results follow renal decapsulation.

A New Form of Vaginal Speculum.

Dr. HUBERT ROBERTS exhibited a modification of Sims's duck-bill speculum fitted with a flange to the upper blade (see p. 366, where the instrument is fully described).

Sir FRANCIS CHAMPNEYS (London), after apologising for his delay in reaching the section on account of an accident to his train from London, opened a discussion on

The Pathology and Treatment of Asphyxia Neonatorum.

He first discussed the causes of the first breath, and divided these into two groups, viz.: (1) predisposing, and (2) exciting. Of the predisposing causes, the essential factors are canalisation of the cervical canal and diminution in size of the placental site, with its associated diminution in the blood-supply and aeration of blood to the fœtus. This is very pronounced at the birth of the child. Not infrequently a child may not breathe for several minutes after birth, and yet if kept warm is in no danger. It is in reality breathing still through the placenta. Of the exciting causes the impact of cold air is the most important. Reference was made to breech cases, where the child is deprived of both methods of respiration—viz., pulmonary and placental. The speaker recognised two stages of asphyxia—viz., (1) apoplectic, where the child is livid, the muscular tone is not lost and it responds to reflex stimulation; and (2) syncopal, where the child is pale and flabby, muscular tone is lost and there is no response to any reflex. These latter are the serious cases and may be due to pressure upon the brain. Reference was then made to the inspiration of mucus. Before breath is taken all the air spaces are closed. When respiration takes place, lanugo, meconium, &c., may even reach to the pleura. Such cases usually die from a low form of pneumonia. With regard to treatment Sir Francis Champneys emphasised the important difference that exists between "blue" and "white" asphyxia. He discussed the subject under the following headings: (1) The removal of all foreign bodies from the respiratory tract; (2) means to secure the patency of the air-passages; (3) stimulation of the circulation; and (4) means to procure thorough ventilation of the lungs. To effect the first object he recommended that the child be placed on its back, the head extended, and the trachea gently stroked upwards, a finger being placed at the orifice of the trachea. Patency of the air passages may be secured by the passage of a catheter. The circulation may be stimulated by pressure over the præcordium. The importance of friction over the spine was also emphasised. Ventilation of the lungs might be procured by the time-honoured methods of Silvester or Schultze. The speaker asked the members to note that the normal position of rest in the child's thorax was one of expiration. If Silvester's method was adopted, the arms should be everted and seized above the elbows. Schultze's method had the disadvantage of possibly causing internal lesions, but it certainly might procure patency of the air-passages when other methods failed. Furthermore, it procured descent of the diaphragm as in normal respiration. The method should be carried out properly if at all, and Sir Francis Champneys insisted upon the importance of simply steadying the child's body and *not* grasping it. Of other methods, reference was made to insufflation and rhythmic tongue traction. In conclusion, the speaker urged his hearers: (1) Never to hurry; (2) to employ sound judgment as to whether the case is one of pale asphyxia or true death; and (3) to persist in treatment over a sufficient length of time.

Dr. SPENCER observed that in his opinion the shock and anæmia of the "syncopal" type of asphyxia were in reality due quite frequently to visceral injury produced during birth. This he had shown by post-mortem examination. He quite agreed that spinal friction was a valuable asset in treatment. He also placed considerable reliance upon intratracheal catheterisation. He condemned Schultze's method of artificial respiration as distinctly dangerous. The use of oxygen had given good results in his hands.

Dr. HELLIER considered that Schultze's method was dangerous in the extreme. He advocated the teaching to midwives of Silvester's method only.

Dr. WILSON professed himself as a great advocate of the warm bath, and if some method of artificial respiration that could be carried out in the bath was devised he thought that it would have a wide application.

Dr. ROBERTS drew attention to the asphyxia of children after Cæsarean section, and observed that this could not be due to interference with the placental circulation as it was immediately under the eye of the obstetrician. He agreed with Dr. Wilson as to the importance of the warm bath.

Dr. BUIST demonstrated his application of Schultze's method of artificial respiration, and said that if this was properly carried out no great force was required, and that many of the so-called "dangers" disappeared.

Professor STRASSMANN said that when Schultze's method was properly performed a distinct wheezing inspiration was audible.

ODONTOLOGY.

WEDNESDAY, JULY 26TH.

President, Professor FRANK EARLE HUXLEY (Birmingham).

The PRESIDENT having welcomed the visitors and given a brief outline of the programme of the section,

Mr. R. J. ERSKINE YOUNG (Liverpool) opened a discussion on

Dental Diseases from the Physician's Standpoint.

He said that oral sepsis struck at the very root of national health, giving rise to septic anæmia and other constitutional disorders. Appendicitis might be due to oral sepsis through a carious condition of the teeth; tuberculosis, too, might gain an entrance to the system through the exposed pulps of carious molars. He pleaded for a better education of the people on this matter through the medium of the intelligence and sympathy of the daily press. Preventive dentistry was all-important. There was a necessity for legislation regarding the use of local anæsthetics, and a greater knowledge and interest on the part of medical men in connexion with conditions of the mouth which gave rise to severe constitutional disturbances. He narrated his personal experiences as a dental officer in Liverpool.

Sir VICTOR HORSLEY (London) considered that it was through the Section of Odontology that the British Medical Association could speak to the great British public. In London 750,000 children required dental attention and treatment. This could only be gained by the establishment of school clinics. A forward movement on the part of the British Dental Association was required for the enlightenment of the school clinics committees. Dental treatment meant the inauguration and equipment of at least 100 clinics in London. It was the most important national question of the day. He thought that the section should pass at its closing meeting a resolution dealing with the matter, and considered that there should be a closer coöperation between the professions of medicine and of dental surgery.

Mr. C. E. WALLIS (London) dwelt on the need for the conversion and instruction of the members of the education committee of the London County Council, and advocated the delivery of lectures to members of that committee, to parents, and to members of the medical profession.

Mr. H. R. F. BROOKS (Banbury) spoke of the financial difficulties connected with the work, and believed that the solution would be found in State dentistry. The principles of the National Insurance Bill now before Parliament should be extended to the dental side of the question.

Mr. YOUNG replied.

A paper entitled

Dentistry and the Public

was read by Mr. CYRIL HOWKINS (Birmingham), who emphasised the necessity of the elementary school children receiving early dental attention. This was called for from three directions: (1) the general physique of the child; (2) the educational standpoint; and (3) the future of the individual. The after-history of over 3000 children of Birmingham showed that the general physique and health of a child vastly improved after dental treatment. The child was also brighter and got on better at lessons, and rarely stayed away from school from a dental cause. The future of a child who was dentally well equipped on leaving school must be far better than one who laboured from the disadvantages and dangers of oral sepsis. Regarding cost, this might be divided into two parts—capital outlay and annual expenses. The former depended upon different circumstances; roughly, however, about £75 should equip a small house as a school dental clinic. The annual expenditure would be about £450 a year, including £300 stipend for the dentist. The remaining £150 would cover rent, rates, taxes, payment of caretaker, gas, fuel, water, dental materials, &c. From the statistics worked out from the Birmingham dental clinic it appeared that about 3000 children might be attended to every year by a full-time dentist. Mr. Howkins thought that six hours a day was as long as one dentist could conveniently work as a rule on account of the difficulty of dealing with young children.

Mr. W. BOWATER (Birmingham), Mr. HAROLD ROUND (Birmingham), Mr. R. W. CLAYTON COOPER (Birmingham), and Mr. YOUNG joined in the discussion.

Mr. HERBERT SMALE (London) and Dr. D. W. CARMALT JONES (London) contributed a joint paper on

The Bacteriology of the Tooth-brush.

They said that a tooth-brush became septic after once using, each hair becoming an inoculation needle, and the person using it might be vaccinated with such germs as flourish upon it. It might be the origin of pyorrhœa alveolaris with its attendant sequelæ of anæmia, gastritis, arthritis, &c. Tooth powders and pastes as usually used did not render the tooth-brush aseptic, 1 in 20 of carbolic acid not being an effectual germicide. All tooth-brushes should be boiled for five minutes before and after use. A new tooth-brush could be used each day, penny ones sold at penny bazaars being good enough for the purpose. Trikresol (1 per cent.) should be used for rinsing the brush, which should be allowed to stand, when not in use, in 10 per cent. formalin solution. A thin quill tooth-pick and floss silk for the removal of the scurf of Leuwenhoeck were essential for cleanliness. No means had suggested themselves of rendering the mouth an aseptic cavity, nor had any profound disappointment been excited on that account. But, a septic cavity notwithstanding, it is undesirable to use a septic instrument for the scarification of the gums, thereby forcibly driving septic micro-organisms into the tissues at the point of the bayonet. It would seem that the use of 1 per cent. trikresol was a simple and accessible method of rendering the tooth-brush free from the commoner pathogenic organisms. The experiments carried out for this paper seemed to lead to the foregoing conclusions.

The PRESIDENT took part in the ensuing discussion, which was continued by Mr. DOUGLAS P. GABELL (London), who strongly deprecated the use of an antiseptic spray in the mouth.

Mr. A. HOPEWELL-SMITH (London) said that india-rubber tooth-brushes were to be obtained which could be thoroughly cleansed at once by washing under a stream of water, and possessed no properties of retaining bacteria on their surfaces. If the bristles of ordinary brushes carried such numbers of bacillary colonies as had been mentioned, their sockets in the tooth-brush itself must be still more numerously and dangerously infected. Mechanical cleansing only of the mouth, he asserted, was necessary in ordinary circumstances, and antiseptic mouth-baths, pastes, &c., never required except in the case of diseased conditions of the mouth and after operations on the jaws. The weak antiseptics found in mouth-baths were of no value whatever in destroying the action of pathogenic micro-organisms in the oral cavity.

Mr. A. W. WELLINGS (Birmingham) described with Mr. C. W. RANDALL (Birmingham) a case of a patient with

Hypertrophy of the Gingival and Alveolar Margins of the Jaws associated with Pyorrhœa Alveolaris.

The patient was exhibited and examined by members. Radiographs and other lantern slides were shown in illustration of the case.

Mr. HOPEWELL-SMITH inquired if sections of the tissues had been cut and examined microscopically; if so, what they showed, and if the Saccharomyces mycoderma was present? It had been affirmed by an American author (Roe) that this bacterium was the cause of the disease. He thought that the species of bacteria, photomicrographs of which had been thrown on the screen, appeared to be the usual pathogenic and pyogenic organisms associated with diseases of the gums and alveolar processes of the jaws.

The discussion was continued by Mr. GABELL, the PRESIDENT, and Mr. J. E. PARROTT (Birmingham).

OPHTHALMOLOGY.

WEDNESDAY, JULY 26TH.

President, Mr. HENRY EALES (Birmingham).

The PRESIDENT said that he wished to give a hearty welcome to all those ophthalmologists who had favoured them with their presence. He was glad to see so many, and he ventured to think that their expectation of the presentation and discussion of a series of valuable papers was destined to be fulfilled.

Professor PRIESTLEY SMITH (Birmingham) opened a discussion on

The Operative Treatment of Glaucoma.

He said that at the outset he would put certain questions to them as an indication of the lines upon which his paper would run. Ought they to depart from the time-honoured operation of iridectomy of von Graefe in the treatment of glaucoma? And, if so, what other and new operation should replace it? The purpose of operation he held to be the establishment of the filtration of the accumulated fluid within the eye; either normal filtration should be restored, or abnormal filtration should be set up. Experience had shown that the area of their operation was strictly limited. It must be at the site of normal filtration. Posterior sclerotomy, posterior trephining, and tapping the anterior chamber were all proved to be only temporary means of reducing tension. That being so, the anatomical characters and variations of the site of operation became important. He showed that the extent to which the limbus overlapped the filtration angle differed in different persons, and also in the same eye, for the overlapping was more marked above and below than laterally. Also the relation of the lens to the circumlental space varied; even with the same sized lenses it was larger in some eyes than in others. If this were so in normal health, it must be even more marked in congestive glaucoma. With the aid of a series of lantern slides of sections of healthy and glaucomatous eyes he illustrated these points. Considering operative measures, he held that the object of iridectomy was the restoration of the normal outlet of the aqueous, and the clinical manifestations were that this was secured in the greater number of cases of acute glaucoma. There were a few such cases in which happy results were not secured, and they were accustomed to describe this as "malignant" glaucoma, a convenient cover for a disastrous result. In his experience posterior scleral puncture preceding the operation for iridectomy was a most beneficial proceeding; it slackened the tension of the eye, lessened the risks of the sudden loss of tension at the moment of the larger incision into the globe, and it in no wise increased the difficulty of the iridectomy. In other conditions, or in such cases where they had failed to restore the normal outlet of the aqueous, they must look to the production of artificial outlets, "cistoid scars"; of these conditions chronic glaucoma was the most important. In congestive attacks it was possible to reopen a freshly blocked filtration angle, but in chronic glaucoma there were adhesions, perhaps sclerosis, so a normal track was impossible. The possibility of securing abnormal filtration routes was not a new idea—it had been recognised by de Wecker; in recent years most valuable work had been done by Herbert, Lagrange, Elliot, and Fergus in

the systematic production of such abnormal routes for filtration. These results had placed within their hands a series of excellently conceived and well-established operations from which it was possible for them to make choice. His own experience had been confined to Herbert's original "wedge" operation, a modified sclerectomy, and in his experience it was all that could be desired, the results were most satisfactory and the failures few. For early acute glaucoma he still thought that iridectomy was a good and successful operation; he did not like the idea of trephining down upon the swollen base of the iris and turgid ciliary processes. But for chronic cases he thought these new modes for the production of an artificial route of filtration excellently designed, and in their effects superior to iridectomy.

Major R. H. ELLIOT, I.M.S., followed with a paper entitled

Observations on Trephining the Sclera.

The simple trephining operation he advocated had now been performed in 403 cases in Madras. By this means they established a direct entry into the anterior chamber with the least possible disturbance of the iris and surrounding tissues. He was in the habit of turning forward a large conjunctival flap and continuing the dissection so as to split the cornea for the depth of 1 mm.; then the trephine was used to cut out a small disc, half cornea and half sclera, from the margin of the limbus. In his experience a trephine 2 mm. in diameter was the best. Care must be taken not to buttonhole the conjunctival flap. As regards the risks of the operation, the disc might fall into the anterior chamber if too much force were used; in his experience the accident did not matter, and it was unwise to seek to remove the lost disc. In 5 per cent. of his cases there had been escape of vitreous, 16 of them in desperately bad eyes where every risk was intensified. In nearly 50 per cent. of cases iridectomy had been done conjointly with the trephining. In some cases this procedure had been followed because the iris tended to advance into the hole, but that was not always so. For secondary prolapse iridectomy had been done in seven cases. He was disposed to perform iridectomy in most cases merely as a mechanical safeguard, and not as enhancing the effects of the operation. He then showed by means of diagrams the different effects of the trephining, according as the state of the angle of the anterior chamber and the position of the root of the iris varied. In conclusion, he maintained that granting the necessity for removing a piece of the sclera to establish filtration or filtering scars, trephining was the simplest and best operation.

Dr. J. GRAY CLEGG (Manchester) continued with a paper entitled,

Observations on Trephining the Sclera.

In recent years he had done several operations other than iridectomy for chronic and acute glaucoma, such as Gayet's, Herbert's wedge operation, and Lagrange's operation, but with only moderate success. The reaction from these operations was rather violent, and there was some uncertainty of the size of the sclerectomy in the last-named operation. Succeeding these operations he had performed trephining 23 times with the most satisfactory results, and he considered this operation suitable for all types of primary glaucoma. The improvement obtained in visual acuity was striking, such a change as the restoration of 6/6 vision after it had been reduced to "fingers" was not rare. As to the risks of the operation, he had found few: there had been no escape of vitreous; prolapse of the iris at the moment of trephining had occurred four times, necessitating iridectomy; there had been secondary bulging of the iris once, and of the ciliary body twice.

Mr. C. DEVEREUX MARSHALL (London) said that in his experience malignant glaucoma did not occur if preliminary posterior sclerotomy was performed. For acute glaucoma his inclination was distinctly in favour of iridectomy in preference to any other operation; it had stood the test of time in the way no other operation had, and its results were uniform and good. He had performed Herbert's small-flap sclerotomy many times and with most satisfactory results; but whilst admitting that freely, they had yet to wait to ascertain the permanency of its effects. Trephining he had no experience of, but the results advanced by Major Elliot were good reasons for utilising the method.

Mr. THOMSON HENDERSON (Nottingham) said that their practice must be based upon a rational physiology; the success of iridectomy as a means of relieving tension was established, but it was originally an empirical procedure, and it remained for them to put it upon a rational basis. That basis could only be done by an investigation of the circulatory conditions of the eye, such as he had indicated in his experiments and the deductions therefrom, and the experiments upon cerebral and ocular circulation by Dr. Leonard Hill.

Mr. H. HERBERT (Nottingham), discussing the appearance of scars after iridectomy for glaucoma, said that only those scars which were invisible, or nearly so, could with safety be asserted as solidly knit scars. It was possible in almost all other scars to show that over them there was an abnormal conjunctival œdema—i.e., that there was filtration from the eye through the scar into the subconjunctival tissue. He showed a section of a "small-flap" wound in which the scar was partly filled with loose fibro-cellular tissue and in which serial sections had proved the absence of any fistula, yet in that eye there had been œdema over the scar. It was confessedly easy to obtain a reduction of tension in an eye by cutting widely into the sclera, but the defect of that procedure was the want of control in the degree of reduction, the eyes tended to get soft. The question was how could they best secure control over filtration, by sclerotomy or sclerectomy? He thought by sclerotomy. As yet the method was in its infancy and its possibilities had been imperfectly explored. For instance, numerous modifications of the small-flap operation at once suggested themselves should variation prove necessary. In hard, blind eyes sclerotomy at present often proved efficient only in removing pain, the tension being imperfectly reduced at least for a time. And there were a few secondary glaucomas in which the need of freer filtration was obvious.

Mr. F. RICHARDSON CROSS (Bristol) said that without question physiology and pathology must be at the basis of their conception of treatment. In his view the work of Weber and that of Priestley Smith had established the primary facts of the importance of the filtration angle; and whilst he congratulated Mr. Henderson on his work and hoped he would continue it, as yet he could not say his faith in the older theories was disturbed. In acute glaucoma there could be no question that iridectomy was the best operation, and that operation was the only treatment. Chronic glaucoma was a different condition; the most perfect iridectomy might fail to relieve the tension permanently. He had always tried to make his incision a long shelving one, commencing, say, 2 mm. back from the limbus. In a number of cases of hydrophthalmos he had had remarkably successful results by doing Herbert's small flap sclerotomy with Bishop Harman's "twin scissors," and he was of opinion that for these cases it was preferable to iridectomy. As a rule, he should continue to do iridectomy in simple and chronic glaucoma, as well as in acute cases; but should tension recur he should use the sclerotome, preferably Bishop Harman's.

Dr. ADOLPH BRONNER (Bradford) said he had tried various methods of operating for glaucoma. In acute and subacute conditions he performed posterior sclerotomy first, if possible, and then iridectomy. If tension recurred he used the trephine. In chronic cases he still preferred iridectomy, except in cases of arterio-sclerosis with increased blood pressure in feeble and nervous patients—then he trephined. He showed a modified form of trephine which he found convenient in use; it had an outer sheath which steadied the trephine in boring and prevented wobble.

Mr. N. BISHOP HARMAN (London) said no speaker had as yet considered the various merits of these operations from the patient's point of view. Granting for the sake of argument equal value in iridectomy, sclerotomy, and sclerectomy, which operation was most commendable from the point of view of the patient's general condition? For acute glaucoma he believed in a wide iridectomy; the condition was severe, and demanded an operation which even though severe was undoubtedly reliable. In chronic glaucoma the case, although serious enough, did not present so formidable an aspect to the patient's mind. The loss of vision might be small or only occasional, even the field might be but little affected; in such a case an iridectomy, with the necessarily wide laying open the eyeball, strict confinement in bed for at least a week, the certainty of considerable resultant astigmatism, presented no attractive prospect. The confinement in bed alone was a serious item in old folk with feeble hearts

and circulations, and there is no doubt these considerations had deterred not a few surgeons from advising operation in times past and had favoured the use of miotics. Contrast with the risks of iridectomy the simplicity of the procedure in Herbert's operation, the one with which he was familiar—the advantages were manifest. There need be no pain at the operation; the risk of injury to the eye was the smallest; he had no hesitation in permitting patients to sit up in bed the day after the operation, so that the disturbance of an old person's condition was the least possible; very little, sometimes no, astigmatism was caused by the operation; and lastly, in the event of a failure to secure a permanent lowering of tension it was easy to repeat the operation, indeed, he proposed this week to do a third operation upon a patient in whose eyes the benefit of the previous operations had not been maintained. This particular case was of interest; the man's sclerotics were extraordinarily tough and gristly, so that the flap produced had very little pliability. He thought that in such cases the tip of the flap should be excised, as had been suggested by Herbert. The differences of the texture of the sclerotic and its effects upon operative procedure were worth considering.

Mr. W. H. H. JESSOP (London) said that the discussion was one of the greatest importance. He considered there were great differences in acute and chronic glaucoma. In acute the large peripheral iridectomy, preceded, if necessary, by a posterior scleral puncture, was the proper procedure. In chronic glaucoma iridectomy was frequently of little use and even dangerous, and it was in these cases he now performed Herbert's sclerotomy in preference to that of Lagrange. He had no experience of trephining, but intended to try it.

Mr. CHARLES WRAY (Croydon) said that, admitting all that was claimed for the new operations to be true, his early experience of operations in chronic glaucoma left him credulous of the advantages of operation over the continued use of miotics. He had cases which had maintained their stand for 15 to 30 years, and that without risks, such as soft eyes and detached retina.

Dr. T. HARRISON BUTLER (Coventry) had tried Elliot's operation with satisfactory results. He had had difficulty in getting trephines that would cut; so far Freeland Fergus's had proved the best. He had had difficulty by reason of the disc of tissue falling into the anterior chamber. One point he thought should be called attention to, and that was the grave risk attaching to operations upon eyes in which the periphery of the field approached the fixation spot; operation might secure permanent fall of tension, but it was liable to cause loss of macular vision. On the matter of the circulation of the eye, it was interesting to note that a recent German author had brought forward a series of observations upon which he based the thesis that there was no interocular circulation! Then there were the observations of Professor Arthur Thomson, which indicated that circulation might be limited to the small pump-like action of the scleral spur.

Mr. J. JAMESON EVANS (Birmingham) said he had looked up the hospital notes of the last two or three years' cases of glaucoma. He found 9 acute and 3 absolute cases, for all of which iridectomy was performed; 5 subacute and 33 chronic cases, for which filtration operations were done, half Herbert's wedge, and the other half trephining. His general conclusions were in favour of iridectomy for acute glaucoma and trephining with or without iridectomy for chronic cases. Trephining was, in his experience, the easiest operation and caused the least reaction; it was easy to repeat, and it caused no disfigurement.

Mr. WILFRID ALLPORT (Birmingham) had performed 40 operations after the fashion of Herbert's wedge-operation, mostly in chronic cases, with excellent results in every case. For acute glaucoma no scleral operation was so satisfactory as scleral puncture followed by wide iridectomy.

Mr. JOHN HERN (Darlington) said that were he to put himself in the position of the patient, as suggested by Mr. Harman, he would certainly prefer a wide peripheral iridectomy for acute or chronic glaucoma in preference to any of the newer scleral operations. With the incision placed well back in the sclera, as had been described by Mr. Cross, there was the best guarantee of success.

Dr. A. F. MACCALLAN (Cairo) said the condition of the iris should determine our choice of operation. If the iris was atrophied, then the possibilities of absorption were diminished, so that something else than iridectomy was required.

Mr. CLAUD A. WORTH (London) said in his view atrophy of the iris was not so important as the possibility of the existence of adhesions of the iris at the filtration angle; where these existed iridectomy was almost certain to fail.

Dr. H. SECKER WALKER (Leeds) said that for acute glaucoma he believed in iridectomy, but he had no faith in it for chronic glaucoma. He got better results with Lagrange's operation than with iridectomy, and better still with Herbert's operation. The small flap operation he found comparatively easy to do, quite painless, it gave excellent results, and it could be repeated in case of only partial success.

The PRESIDENT recalled the days when cocaine was unknown, and how on occasions they had to perform iridectomy in acute glaucoma without even a general anæsthetic; once he operated on both eyes at one time.

Major ELLIOT, in reply, maintained that the success of iridectomy lay mainly in the procuring filtration through the scar. This could be determined quite easily when it was specifically looked for; it was as easy to find as pitting of the shins in œdema of the legs. He advocated trephining for acute as well as for chronic glaucoma; he maintained that it was a safe proceeding, which iridectomy was not. It was not necessary to perform scleral puncture to make it safe or enable it to be performed, as had been acknowledged by some speakers. In fact, the harder the eye the easier the trephining, and there was no risk with ordinary care that the aqueous would escape too rapidly. The occurrence of quiet iritis had been referred to; it certainly followed trephining, though he doubted if it was true iritis, but it could be prevented by the routine use of atropine on the third day. Iridectomy he held advisable in trephining, but merely for its mechanical effects. As to the discussion between Herbert and himself, it came to this: Herbert considered trephining did too much, whilst he (Elliot) thought sclerotomy did too little. He could confirm Mr. Harman's observations concerning the differences in the texture of the sclera of patients.

Dr. CLEGG, in reply, considered trephining good and safe for acute glaucoma, and instanced his four successful cases.

Mr. PRIESTLEY SMITH, in reply, said he had a great admiration for Mr. Henderson's work, but could not follow him in his conclusions that cerebral and ocular pressures were always the same. Did he mean that when ocular pressure was thrice what it ought to be the brain was subjected to a similar excess pressure and without any symptoms? The problem they had to consider was how to secure a filtration scar that would be the best for the majority of cases. Lagrange, Elliot, and Fergus removed pieces of the sclera; Herbert displaced a piece. The apparent test was the production of œdema. The true test was not apparent œdema, nor the tension, nor visual acuity, but the field of vision as mapped with the perimeter.

PATHOLOGY.

WEDNESDAY, JULY 26TH.

President, Professor R. FRASER CALDER LEITH (Birmingham).

The PRESIDENT, after a few words of introduction, mentioned with regret that Professor Charles Richet was unable to be present, and as he had not sent his paper the following abstract was read: 1. The penetration into the blood of a heterogeneous (= native) albumin—that is, of one not altered by digestive processes—produces a special state of hypersensibility to this same albumin: this is anaphylaxia. 2. Anaphylaxia by digestive channels (or in other words alimentary anaphylaxia) is due to some ingested albumins not having been sufficiently elaborated by the digestive juices. 3. The anaphylactic state can only be explained by the presence in the blood of a special non-toxic substance, but capable of giving, with antigen, an extremely toxic one. This non-toxic substance is toxogenin. Its presence is proved by this, that on mixing the blood of an anaphylactic animal with the antigen one obtains a substance that is immediately toxic. 4. Once toxogenin has been formed in the blood, it disappears from it only very slowly, if even it does ever disappear, so that the anaphylactic state continues for weeks, months, or perhaps years. 5. The presence in the blood of a special toxogenin allows one to make for certain diseases a

diagnosis by anaphylaxis, but this requires scientific investigation, for up to the present the cases in which anaphylactic diagnosis is strict, as with tuberculin, are not numerous, but one may suppose that this method will be perfected. 6. One can combat the anaphylactic state by injections, repeated at frequent intervals, of very small quantities of antigen (anti-anaphylaxia). 7. All subsequent injections of serum or of antigen may produce serious accidents if the second injection is made more than ten days after the first. 8. Anaphylactic accidents affect the nervous system especially—for example, cardiac, vaso-motor, and respiratory. 9. "Idiosyncrasy" of the older writers can be explained in great part by previous anaphylaxis, in part by previously acquired immunities, and partly also by the inheritance of the anaphylaxes and immunities of their parents. 10. Anaphylaxia and immunity are not antagonistic. In many cases immunity and anaphylaxia march side by side after the injection of an antigen.

Dr. WALTER D'ESTE EMERY (London) then read his opening address on

Hypersensitiveness in its Various Manifestations, especially in Relation to Serum, Vaccines, and Tuberculin,

in which, after a brief historical introduction, he drew especial attention to the researches of Arthur on rabbits, in which the anaphylactic reaction to re-injection of serum was mainly local, and to those of Otto, Rosenau, and Anderson on the more sudden and dramatic effects of the injection of serum into a guinea-pig, previously sensitised by a small dose of the same substance, as being the starting points of our knowledge of anaphylaxis. Dr. Emery proceeded to outline the conditions necessary for the development of anaphylaxia. These are the presence of a foreign substance, probably always of protein nature, in the blood or tissues, and a certain incubation period. The incubation period varied according to the size of the sensitising dose, as a rule being from 10 to 15 days, but when large doses were used the period might be as long as 45 days. Dr. Emery mentioned that in Theobald Smith's phenomenon the reaction occasionally occurred in as short a time as half a minute. This depends on the rapidity of absorption, being most rapid in intracerebral injections, next in intraperitoneal and in subcutaneous injections. The possibility of anaphylaxis to non-protein substances, such as iodoform, was discussed, and the suggestion that these acted by splitting up the proteins of the body and thus giving off proteins which did not occur normally was adopted. As regards the symptoms which occur on re-inoculation in man, Dr. Emery pointed out that the symptoms resemble Arthur's phenomenon in rabbits rather than the intense shock which occurs in guinea-pigs, and that the differences in the phenomena might be caused by the rapidity with which the protein gained access to the brain, as shown by Baldwin in the case of tuberculoprotein. Dr. Emery remarked that all parts of the tissues were involved in anaphylactic shock. There were nervous, respiratory, circulatory, alimentary, and cutaneous symptoms. With regard to serum disease in man, he alluded to its connexion with asthma and its possible causation in some cases by previous sensitisation of the patient by eating horseflesh. Dr. Emery called special attention to the local reaction observed after repeated re-inoculation of serum at the same site of inoculation or in places in which previous injections had been made. He mentioned that there were no data as to the duration of the anaphylactic state in man. Periods of from one to nine years were known in guinea-pigs; in man it sometimes lasted as long as three years. In rabbits it generally lasted a matter of weeks. White mice were not susceptible. The anaphylactic condition could be avoided by: (1) giving series of injections at short intervals; (2) giving minute doses of antigen; (3) by heating the serum; (4) by anæsthetising the guinea-pig before inoculation; and (5) by giving doses of calcium chloride, &c. Dr. Emery believed in the beneficial effect of calcium chloride in preventing serum sickness. He also made brief reference to the rôle of anaphylaxis in general medicine in cases of food poisoning, susceptibility to certain drugs, &c., and in tuberculosis and other infective diseases.

Dr. SCOTT (London) then proceeded to discuss the source and probable nature of the anaphylactic poison. The poison responsible for symptoms of anaphylaxis, the anaphylactin in Friedberger, is regarded by him as being derived from the various antigens which are capable of setting up the supersensitive state, the hypothesis being that the complement acts as the antigen through the intermediation of an antibody, probably the ordinary amboceptor, precipitin, or lysin. The possibility that it is not the antigen but the amboceptor, normal or immune, which provides the poison must be considered in the light of the experiments of Keysser and Wassermann. These observers have prepared anaphylatoxin by digesting inorganic suspensions—kaolin and barium sulphate—with fresh guinea-pig serum. Here no antigen is present. Normal amboceptor is apparently the only substance capable of providing the toxin.

Professor G. SIMS WOODHEAD (Cambridge) continued the discussion. He stated that 15 years ago, when working with some diphtheria and other antisera, a batch of guinea-pigs which had been previously used all died from subsequent inoculation. In the light of recent work he now recognises that they were typical instances of anaphylaxis. Further, when working with "serum toxin" as introduced by Cartwright Wood, they sometimes gave injections of unheated serum toxin, and these injections were followed by complex symptoms which may be compared to Arthur's phenomenon, and he felt sure that they were producing local anaphylaxis. He agreed with Dr. Emery that the lytic changes in the cells and solid tissues must be taken into consideration, even though they might not be so important as those associated with the body fluids.

Professor A. S. F. GRÜNBAUM (Leeds) stated that in certain cases anaphylactic phenomena had appeared in man after the sixteenth or later injection of antituberculous serum in relatively large doses. This is not easily explained by current theories. Antitoxin itself did not play any part in the phenomenon of anaphylaxis, and he thinks that disease might modify the anaphylactic state. He quite agreed that keeping the serum diminished the amount of anaphylaxis. Was this the result of loss of complement? He suggested that the following facts require taking into account: (1) nature of disease; (2) age of serum; (3) probability of presence of toxin in the serum; and (4) possibility that repeated injections of serum acted like repeated injections of bacterial vaccine, and produced a negative phase.

Dr. GOODALL (London) asked Dr. Emery whether serum disease in man meant anaphylaxis. In his experience the usual result of giving serum in man was negative in about 70 per cent. of cases. Some got serum disease generally in from seven to nine days or up to three weeks. Sometimes symptoms came on immediately after the second injection, and again sometimes in a day or two. He drew attention to the frequency with which those who suffer from asthma get serum sickness. In fact, he would not advise anyone to have serum who suffered from asthma. He stated that he had seen serum sickness simulate measles very closely. He noted that patients suffering from diphtheria who got serum sickness did very well. Serum sickness, in his opinion, is less frequent now than formerly.

Dr. JAMES RITCHIE (Edinburgh) stated that he was anaphylactic to animals, and that the smell of such an animal as the horse gave him bad attacks of asthma. He had been exposed to the action of tetanus toxin, and as a result had injections of antitetanic serum. In about two hours he had an attack of asthma with severe urticaria. He would not again use antitoxic serum without considerable hesitation. He then detailed his work with Dr. Miller on the complement fixation test in tuberculous cases. The method he used was an elaborated Wassermann. His clinical experience went to prove that cases treated with tuberculin did better than untreated cases. Cases which gave the complement fixation test always proved to have multiple foci.

Dr. EMERY replied briefly to the questions asked, and stated that persons fed on raw horseflesh and the expressed juices always had serum sickness when tested with an injection of horse serum. He thought that probably there is more horseflesh eaten than is suspected. Boiling does not destroy its power of sensitising animals, though it destroys it sufficiently to make it impossible to test for it.

STATE MEDICINE AND INDUSTRIAL DISEASES.

WEDNESDAY, JULY 26th.

President, Professor ALFRED BOSTOCK HILL (Birmingham).

The PRESIDENT, in the course of his introductory remarks, said that in a public health sense, tuberculosis was the one pressing problem ready to be dealt with by every means in

their power. There was another point on which he thought a word not out of place. That was the marked change which had taken place both within and without the profession in the conception of State medicine and State hygiene. Intimately associated with the work of the hygienists was that of amelioration, in which all branches of the profession must take part if the national work was to be done satisfactorily. It was absolutely essential for their work that they should carry with them public opinion. The public must lean on the dicta of the physician and surgeon, but they would not lean on the dictum of the medical officer of health—the man in the street would not—until they were sufficiently educated and convinced of the importance of the work. Therefore, one of their principal duties at present was the education of the public in matters of hygiene.

Dr. JOHN ROBERTSON (Birmingham) read a paper on

The Notification of Tuberculosis.

He said that the most important objective in the prevention of disease was an accurate and speedy method of ascertaining where disease existed. Little or no value could be attached to notification if nothing followed the receipt of it. There must be machinery not only for prevention but also for treatment. He thought the Local Government Board had acted wisely in delaying general compulsory notification, because little or no means were in existence for dealing with patients in the direction of cure or prevention. Provided that they had the machinery for dealing with the notified case, and that they did not harm the patient by bringing down on him all the restrictions which applied to the small-pox patient, there appeared to be a necessity for compulsory notification, not only that their statistics should be as complete as possible, but that the exceptional patient should not be able to raise an action for damages which he alleged to be due to notification. There was one objection to compulsory notification which did not now exist. He referred to the practice of not telling the patient the true nature of his disease. The medical attendant must do this now if the patient were to be treated by modern methods.

Mr. A. E. LYSTER (Chelmsford) read a paper on

Sanatoriums.

He admitted that sanatoriums must play some part in solving the tuberculosis problem. Those in authority and occupying high places both inside and outside the profession said that the sanatorium was the chief solution of the problem; so much so, that the Chancellor of the Exchequer had announced his intention of spending 1½ millions in one year and 1 million each succeeding year mainly for the provision and maintenance of sanatoriums. Mr. Lyster contended that sanatoriums should occupy quite a subsidiary place in the solution of the problem. It was quite easy to carry out sanatorium treatment in the homes of at least four-fifths of those affected, and this could be done by providing a habitable shelter at home. The utility of the sanatorium was grossly exaggerated. He did not believe the statistics published by sanatoriums; he knew they were untrustworthy and misleading. Their cases were most carefully selected. He treated all his own cases in their own gardens in canvas shelters. No better way could be devised for isolating a sufferer than by isolating him in a habitable shelter in his own garden, where he could be tended by those near and dear to him. He suggested there must be compulsory notification, and then that a habitable shelter should be provided for those who had garden or backyard space. For those who had no such space he suggested that instead of providing sanatoriums every sanitary authority, or, if there was to be a National Tuberculosis Committee with local advisory committees, that such be empowered to purchase land in the vicinity of the town, upon which should be built cottages according to the number of cases; that a small garden should be allotted to each, and that a habitable shelter should be placed in each garden. An allowance should be made to the sufferer according to circumstances.

Dr. R. W. PHILIP (Edinburgh) read a paper on

Tuberculosis Dispensaries.

He said that the great purpose of tuberculosis dispensaries was that there should be no case of the disease, even in its earliest stages, undetected or uncared for. It was best in the interests of the antituberculosis campaign that the dispensary should be constituted a separate institution. To link it with the existing general hospitals was likely to lead to failure and disappointment. He wanted the disease to be taken as a special study worthy of the closest thought and highest effort. There was risk in making the dispensary merely a part of the office of the medical officer of health.

Dr. W. CAMAC WILKINSON (London) said that tuberculin dispensaries offered not only the best but the only means of satisfactorily dealing with the problem of tuberculosis among the poor. It was simple, cheap, effective, and comprehensive. There were 5000 cases in Birmingham urgently needing help, and there was no other way to help them than through tuberculin dispensaries. Sanatoriums only dealt with 10 per cent. of the sufferers, and the amount spent upon them was more than sufficient to provide the best form of treatment for every victim of the disease.

Dr. C. KILLICK MILLARD (Leicester) said that the Corporation of Leicester had just decided by a unanimous vote to start a municipal tuberculosis dispensary. He was satisfied that there was nothing antagonistic between sanatorium treatment and tuberculosis dispensaries, or tuberculin dispensaries. He believed that tuberculin had a great future before it, and if further experience justified present hopes it followed that tuberculin would be used in every dispensary and sanatorium. The health department, guided by the medical officer of health, was necessarily the centre of all effort for the prevention of disease, and he thought it was a mistake to put dispensaries under separate control.

Sir WILLIAM J. THOMPSON (Registrar-General for Ireland) said that since 1907 the death-rate from tuberculosis in Ireland had fallen from 2·7 to 2·3 in 1910 per 1000. This meant 1663 less deaths from consumption, or an average of 32 deaths less per week. The tuberculosis death-rate in Dublin had fallen from 4·6 to 3·7 in the same time. This had been brought about mainly by the work of the Women's National Health Association. A most important work of this association was the "after-care of patients" who had been already at sanatoriums. The association felt that patients very soon lost what they had gained at the sanatorium if they were allowed to go back to the wretched surroundings, but if these patients were encouraged and helped to carry out the sanatorium treatment at home it would put them over that dangerous stage between being discharged and able to take up full work.

Dr. HALLIDAY G. SUTHERLAND (London) said that tuberculin was used in dispensaries both as a diagnostic and therapeutic agent. It was used in selected cases, as indeed it had been in Germany and all over the world, but it should not be divorced from general and medicinal treatment. There was no specific for tuberculosis. Dr. Wilkinson and his school regarded the tuberculin reaction as specific. That was quite wrong. It had been absolutely proved that the reaction occurred in typhoid fever, measles, pneumonia, and syphilis. Further, 70 per cent., even of a healthy German cavalry regiment, reacted to tuberculin. If they had gone to Dr. Wilkinson no doubt they would have added to his list of cured. It was a great mistake to divorce tuberculin from other forms of treatment.

Dr. R. MURRAY LESLIE (London) said that they were in agreement with Dr. Philip in regard to the paramount importance of domiciliary visitation in the prevention of tuberculosis, and he would specially draw attention to the valuable work in this connexion done in the rural districts by the caravan crusade against tuberculosis carried out in recent years by the National Health Association of Ireland and the Women's Imperial Health Association of Great Britain. At the best, sanatorium treatment was only suitable for a small fraction of the cases, the great bulk of which must be dealt with by agencies such as anti-tuberculosis dispensaries. Tuberculin treatment was simply one of many methods which had its due place in the treatment of this disease, and if scientifically valuable would be used in tuberculosis dispensaries, sanatoriums, and elsewhere.

Sir WILLIAM OSLER (Oxford) pleaded for the association of the tuberculosis dispensary with the general hospital and county infirmary.

Dr. J. C. MCWALTER (Dublin) said that the ordinary opinions as to sanatoriums were based on fallacies. It would cost at least £40,000,000 a year to treat all the cases of tuberculosis in Great Britain. The Chancellor of the Exchequer was about to allow only £1,500,000 a year. It would be far cheaper to have convalescent homes where a

patient could be treated in the pretuberculous stage. They ought to hesitate before placing a burden on the ratepayers, because the great cause of sickness was poor food and bad housing.

Dr. IDA E. FOX (Ashover Sanatorium) spoke about the home treatment of tuberculosis, and said it was of little use unless preceded by sanatorium treatment.

Dr. W. B. KNOBEL (Belbroughton) said that the cause of phthisis was infection plus loss of immunity; that infection was to be found especially in milk. Loss of immunity produced by bad hygiene or some other condition occasioned the disease. The cure of phthisis lay in a restoration of immunity, and the permanence of the cure depended upon after-care, in which the tuberculosis dispensary was of great value. Many cases were undoubtedly cured by tuberculin alone, but many were cured by sanatorium treatment alone. More than these together could be cured by sanatorium treatment plus tuberculin, and more still would be cured by those two plus some method of dealing with secondary infections.

Dr. A. H. BYGOTT (Barking) said that the medical officer of health did not want to interfere with the person who conducted the dispensary; his object was simply to coördinate the work with others, and it was desirable that he should do so.

Mr. H. J. EGERTON H. WILLIAMS (Sheffield) said that it seemed to him that in the present state of their knowledge and the difficulties of coming to a conclusion as to whether this or that case was cured, it was sufficient for corporations to undertake the education question for the present.

The PRESIDENT, in conclusion, said that sanatoriums alone did not solve the problem, and the same might be said of the tuberculosis dispensary of Dr. Philip, the tuberculin dispensary of Dr. Camac Wilkinson, and the shelters of Mr. Lyster—all were useful under certain conditions and could not be neglected, but by themselves had only limited applications.

Dr. F. E. WYNNE (Leigh, Lancs.) read a paper on

Domestic Hot-water Supplies as a Factor in the Production of Lead Poisoning.

He said that he wished to draw attention to the enormous excess of lead which he found in samples taken from the hot-water taps of private houses. In 30 observations of water taken from houses in all parts of the borough of Leigh there was invariably lead in the sample taken from the hot tap, even when the cold water showed none, or only a trace. In several cases the hot water contained over 2 grains of lead to the gallon. A similar state of affairs had since been observed at Ashton-under-Lyne. In his annual report for 1910 the medical officer, Dr. J. W. Talent, remarks: "During the year samples of drinking water were tested for lead—25 taken from cold-water taps, 6 from hot-water taps. Of those taken from the cold-water taps, three showed slight acidity, but no lead was present in any. Of the six taken from the hot-water supply, three showed a marked quantity of lead. It is evident that anyone drinking water from the hot-water tap in such cases as the three in question would run a decided risk of lead poisoning. The matter was freely discussed in the local press, and an advertisement pointing out the danger was inserted in the same." This discrepancy in the amount of lead contained in the hot- and cold-water supplies was altogether too great in the case of Leigh water to be accounted for by any possible increase of the solvent power of the water due to its temperature, and it was also out of proportion to the extra length of piping through which the hot water passed. It was clear, therefore, that the hot water was somewhere exposed to lead in a way in which the cold water was not. After a little inquiry Dr. Wynne learned that this contact took place in the so-called copper cistern, the great majority of which were heavily weighted with lead.

Dr. J. BROWN (Bacup) said that Dr. Wynne had done a public service in directing the attention of the medical profession to the danger of the fraudulent use of lead in the cisterns sold as copper. No doubt that accounted for the large amount of lead, viz., 2 grains per gallon, found in some samples. Usually there was a long length of lead pipe to the hot-water tap.

THERAPEUTICS, INCLUDING DIETETICS.

WEDNESDAY, JULY 26TH.

President, Sir ROBERT M. SIMON (Birmingham).

This Section met in conjunction with the Section of Anatomy and Physiology. A discussion took place on

The Merits of a Relatively Low Protein Diet.

Professor CHITTENDEN (Yale University), in opening the discussion, made the following statement:—1. Dietetics as a part of the physiology of nutrition is entitled to the same careful and thorough study as any other branch of biological science, while the opinions and theories connected therewith should be formulated upon evidence that is both comprehensive and reliable. 2. It is a fair argument that the quantity of food consumed daily should be proportional to the needs of the body. In order to avoid excess or deficiency, it is important to ascertain what the real needs of the body for food are; how much food is needed by the average man under ordinary conditions of life to repair tissue waste and to furnish fuel for the required energy. It is not the part of wisdom to accept unquestioningly dietary standards based simply upon the everyday habits of mankind under the assumption that because civilised people make a practice of eating daily a certain amount of food, that quantity must represent the real needs of the body. 3. Various data are presented tending to show that the ordinary conception of the protein requirement of man is an exaggerated one. A large number of data recently collected among the American people indicates that many people at least, apparently in health and vigour, and with ordinary resistance to disease, do live at a much lower level of nitrogen metabolism than the ordinary accepted standards call for. Additional experiments just completed corroborate the view that normal individuals are able to maintain their usual condition of health, with, indeed, more or less improvement, on relatively small amounts of protein food. Bio-chemical study of these individuals shows that their metabolism is unimpaired. The partition of urinary nitrogen, &c., is in nowise disturbed. Utilisation of the nitrogen of the food, as well as the fat, is maintained at the proper level on a relatively low protein diet. 4. Various data from State institutions are in harmony with the view of the adequacy of a relatively low protein diet. 5. Brief discussion of the results presented by other investigators in the study of protein metabolism, as the people of Bengal, leads to the conclusion that the alleged bad effects of low protein intake are not to be associated with the quantity of nitrogen, but with other factors, such as the character of the food, involving its availability, &c. An attempt is made to show the necessity of a ration that is well balanced—one in which the various physiological factors are given due consideration. Nitrogen and calories by no means constitute the only elements to be considered in a so-called standard dietary. Distinction is to be drawn between the needs of a growing organism and the needs of an adult who has attained his growth. The need of protein per kilogramme of body weight in the two cases must be different. Experimental data, however, show that even in the early periods of growth the protein of the food constitutes a surprisingly small part of the diet of the suckling infant. The fully-developed man, having an abundance of fat and carbohydrate in a readily available form to meet the energy requirements of his body, can, it is believed, live with perfect health on a few grammes of nitrogen per day. To serve its full purpose in the economy, however, man's food must be in a form readily assimilable, free from a large excess of indigestible material.

Dr. D. CHALMERS WATSON (Edinburgh) said that the excess of protein commonly taken was disposed of as waste and affected individuals differently. The tuberculous apparently thrived on more, while the gouty tolerated less. A chart was exhibited which showed a progressive increase of meat consumption rising from 3–50 lb. per head during the past 50 years. Experiments illustrating the effect of bread and flesh feeding on animals were cited, showing in the latter an increase in the fæcal nitrogen. Sections of the kidney showed in the bread-fed animals granules restricted to the base of the epithelial cells, while in those on a meat diet the granules were widely distributed in the cells indicating increased functional activity. A further illustration of comparative diet effects was afforded by comparing young

rats of the same age, fed respectively on bread and milk and on meat, those on the carbohydrate diet being half as large again as those fed on meat. Sections through the naso-pharynx showed healthy mucous membrane in the bread-fed rats, but a state of catarrh and shedding of epithelium in those fed on meat.

Lieutenant-Colonel C. H. MELVILLE, R.A.M.C., compared the deductions from experiments and experience, commenting on the limitations and fallacies of the former, and the broad and natural conditions in the latter. He advanced the view that a liberal protein diet was adopted by the conquering races, while these inferior in courage and strength were addicted to a carbohydrate diet, and not the best of that, like the inhabitants of Southern India. Experiments carried out with carefully prepared and regularly administered food in good quantity and of good quality might give good results, even with a small proportion of protein, but taking things as they came and obtaining such food and in such condition as they were able most men required a higher proportion of protein in order to maintain their health and powers. Indeed, it was more a question of quality than quantity, depending largely on the proportion which could be digested and assimilated.

Dr. ROBERT HUTCHISON (London) said he believed that for the average mortal the question of excess of protein was not as important as many appeared to think. Some cranks and faddists assumed a strong attitude against free consumption of protein, but Nature said, "You need not trouble, my children, I have settled this matter long ago." Experience was the best test of truth and constantly exposed the theorists. He characterised the experiments of Dr. Watson Chalmers as "solemn trifling." Apart from the protein factor there were a thousand differences between a meat and lactocarbohydrate diet which he had not taken into account. The diagram representing the supposed increase in meat consumption per head was specially misleading, as it only represented imported meat with a rapidly increasing population and took no account of home-grown flesh food which alone sufficed for the community 50 years ago. Moreover, the increase shown was associated with a progress in improvement in the health of the community. In spite of the relatively low protein equivalent of milk, this represented a high proportion compared to bodyweight in an infant. There was no definite evidence that excess of protein did any harm or was really accountable for the occurrence of gout or renal disease. Could it be said that Professor Chittenden had proved the security of a low protein diet or had disproved the advantage of excess. For there was an advantage in stimulating metabolism which meant fuller life, fuller efficiency, and greater resistance to disease. There might be an economical advantage, a low protein diet was cheaper.

Dr. WILLIAM RUSSELL (Edinburgh), who professed himself a warm disciple of Professor Chittenden, said that in regard to the numbers of persons suffering from protein excess there was presented a scientific basis for conclusions that had been arrived at clinically. He emphasised the special value of Professor Chittenden's work in connexion with groups of individuals continuing an ordinary life and unrestricted diet, though one which was accurately estimated. Physicians had to deal with patients who were often overstraining their powers of assimilation in endeavouring to maintain their strength, and the question to him was, did they need to do so? Apart from other things, there remained the baneful influence of the intestinal effects of excess of protein.

Dr. ALEXANDER HAIG (London) also supported the views expounded by Professor Chittenden. He contended that the habits of mankind could not be regarded as a standard of what was needful and wholesome. The standard to be aimed at was represented by 90 grammes of protein daily, or 9 grains per pound of bodyweight. Any gross deviation above or below this led to ill-health. Relative starvation reduced the output of uric acid, slowed the capillary circulation, caused cardiac dilatation, and impaired the quality of the blood. Much more was needed by the very young. A nursing infant received 31 grains per pound of bodyweight and a child of 12 months 40 grains. This produced a physiological balance. He added, deficiency of salt led to defective formation of hydrochloric acid.

Dr. E. P. CATHCART (Glasgow) insisted that the quality rather than the quantity of protein was important. Experiments on dogs showed that the minimum dietary containing the proper amount of protein was attained with dog's flesh. Throughout the animal kingdom there was idiosyncrasy in relation to food. The protein supplied an important stimulant to digestion.

Dr. A. C. F. RABAGLIATI (Bradford) delivered a very complex statement on the distribution of energy, which was a matter that went much beyond protein metabolism.

Dr. WOODS HUTCHINSON (New York) expressed his sense of the importance of Professor Chittenden's work. There was a wide range in the potentiality of proteins, that of fish being much lower than that of animal flesh. Experiments with isolated lengths of intestine had shown that fæcal matter was not merely the residue remaining in the bowel, but was matter that, having been digested and absorbed, was resecreted into the intestine after rejection in the body, which only selected and retained what was suited to ready assimilation. Experience of food values had been tested through centuries. Nations, classes, and individuals had determined what was most suitable to each. On the whole, it might be said that those most extravagant in the matter of protein consumption were superior in power to others. Japanese vegetarians settled in America improved vastly under a more liberal protein diet, so that whereas on arrival their strength equivalent was only 35 per cent. of a white man it increased with an extended diet to 65 per cent. Excess in meat diet was by no means the only factor in the production of gout, and in regard to kidney affections two-thirds were the result of direct infection. A due proportion of protein and carbohydrates was necessary in all diseased conditions, even diabetes.

Dr. J. HADDON (Hawick) gave his experiences as a fruitarian and vegetarian with great enthusiasm, noting a doubling in the output of urea attending an animal diet.

Dr. A. B. OLSEN (Caterham), speaking of sanatorium treatment, said a vegetarian dietary had been adopted by choice, the protein element being gradually eliminated.

Professor CHITTENDEN, in reply, pleaded for reconsideration and progress in dietetics.

TROPICAL MEDICINE.

WEDNESDAY, JULY 26TH.

President, Sir FRANCIS LOVELL, K.C.M.G. (London).

The PRESIDENT, in opening the proceedings, said he did not propose to give a formal address nor make a lengthy speech. He would confine himself merely to a few words in view of the amount of work which the section had to get through. He could not refrain from referring to the great loss which the Liverpool School of Tropical Medicine had sustained through the untimely death of Sir Rubert Boyce, F.R.S., who had been a prominent worker in that school. He himself could testify to the great advantages which certain colonies had derived as a result of Sir Rubert Boyce's visits. On his advice measures had been initiated which had already borne fruit, and would continue to do so in the future, conferring marked benefits upon the inhabitants of those colonies. The President also alluded to the cordial relations which now existed, and were likely for long to exist, between the schools of tropical medicine in London and Liverpool. Their aims were similar, and in their various researches the workers of the respective schools were constantly in communication with one another with mutual benefit. He congratulated the Liverpool School upon the conferring of the honour of K.C.B. on Professor Ronald Ross.

Dr. CHARLES J. MARTIN (London) then opened a discussion on

Plague—in its Endemiological and Epidemiological Aspects.

He said that as it was necessary to be concise he would confine his remarks chiefly to the occurrence of plague during the last 15 years. He could not marshal all his evidence before them in the time at his disposal nor refer to all the authorities he had consulted. But when the paper he had prepared came to be published it would be found to contain a copious list of references. With the help of lantern slides Dr. Martin showed, along with other views, some maps indicating the various recognised endemic areas of plague throughout the world. In the majority of these animal plague was known also to occur, and in those where rat plague was not reported he thought that closer investigation would furnish proof of its existence. It was hardly possible in the limited time at his disposal to trace how, of late years, plague had diffused itself all over the world. Dr. Martin then paid a tribute to the value of the annual summaries of

the incidence of plague in various parts of the globe begun by the late Dr. Netten Radcliffe for the Local Government Board and continued in recent years by Dr. R. Bruce Low. Appearing in 1894 at Hong-Kong and Canton, the infection in all probability being introduced from the endemic area in the province of Yunnan, plague invaded Formosa in 1895 and reached Bombay in 1896. Spreading gradually over both hemispheres, by 1900 all quarters of the globe became involved to a greater or less extent. The problem was to ascertain how plague had been spread. Bubonic plague was not regarded as directly infective, but nevertheless it was potentially a source of infection. For plague bacilli might settle in the lungs and then be coughed up, infecting the air of the sick room. Some epidemics of pneumonic plague are thought to have started in this way. It was an interesting question how primary plague pneumonia arises. It might start from a secondary pneumonia occurring in a bubonic case, the expectoration of the patient, often suffering from a wandering delirium, being spat all over the bed and the floor or walls of the room, such cases being difficult to control. Afterwards such infection might breed true and produce only pneumonic cases, becoming in this way a man-to-man infection. But the present pandemic of plague had been characterised by a paucity of pneumonic cases. The disease had spread over the world as a bubonic infection. The association of animal plague with that of man had long been recognised, and all authorities were now agreed that rat plague was immediately associated with the development of human plague epidemics. How, then, is plague spread from rat to man? Two suggestions had been put forward: 1. That infected rat excreta deposited on the ground might reach abrasions or scratches on the hands or feet of human beings, and that possibly rat excreta might reach grain and other food for man and give rise to infection through the alimentary canal. Experiments have shown that though these theoretical dangers might exist they could not have played any part in the production of the extensive outbreaks which had occurred of late years. 2. That, as in some other diseases, the plague bacilli were transmitted from animals to man by a suctorial insect; and the insect concerned had been long suspected to be the flea. After referring to the work of investigators in various parts of the world, showing the part played by the flea in carrying plague from rats to man, Dr. Martin related a number of experiments in India devised to show that the flea was the transmitting agent. It had been objected that rat fleas did not bite man, but Liston in India had demonstrated conclusively that the Indian rat flea did bite man when it could not find a rat to feed upon. Moreover, when rats are dying from plague the fleas leave them and seek another host; the more rats that die the more fleas are looking for other hosts; thus man is attacked more frequently during epizootics than at other times. Bubonic plague is caused by the puncture of the skin by the infected flea. General insanitary conditions which foster rats aid in the diffusion of plague. Dr. Martin spoke of infection by clothing sent long distances. In these cases fleas were generally wrapped up in the bundle. The seasonal prevalence of epidemics and epizootics of plague depended on some biological factor. Experiments showed that the number of fleas on rats varied with the season, the maximum number being found on rats in March and April, which in Bombay were the worst months of plague epidemics. Temperature above 85° F. appeared to have the effect of diminishing the amount of plague in India, while a temperature below 80° increased it. Any measures which prevented transmission of fleas to animals would prevent infection by plague. The rat-flea theory, in short, explains all the epidemiological facts.

Professor W. J. R. SIMPSON (London) congratulated Dr. Martin on his able paper. The facts adduced seemed to show the association of human and animal plague with the flea as transmitting agent. His own opinion was that the communication of plague through infected food could not be altogether excluded. Referring again to fleas, he said that rat-catchers in their work got infected by fleas and became infected by plague. He thought, however, that the importance of the flea might be over-estimated and might lead to neglect of other agencies. He compared the importance of the flea in plague to that of the fly in typhoid fever. The theory of insect carriers tinged our ideas. Insects were carriers of protozoal diseases which have a definite life-history in the insect, and such disease could not be spread in any other way, but it might be otherwise in the case of a bacterial infection like plague. He admitted that fleas play a part, but not the whole part, in the spread of plague epidemics. Enough, however, had been proved about the rat-flea theory to make it the basis of administrative action in India. He advocated more application of the accumulated knowledge as to plague, for little effect seemed so far to have followed the measures employed, more than 600,000 persons having died in India from plague in the first half of the present year.

Dr. MAJOR GREENWOOD (London) dealt with some of the statistical points connected with plague prevalences in India. He spoke of the severity of the disease in some Punjab villages and believed that three factors influenced the severity of these local epidemics: (1) the size of the village; (2) the period of the plague season at which the village was attacked; and (3) the situation of the village in the infected area. He thought that perhaps the Indian experience did not apply to all epidemics in other parts of the world.

Dr. F. M. SANDWITH (London) spoke of the behaviour of plague in Egypt. Hitherto the cases in Lower Egypt had been bubonic as a rule; those in Upper Egypt pneumonic.

Dr. H. S. STANNUS (Nyasaland) suggested that congregation of fleas on rats at the breeding seasons might be associated with the behaviour of plague, rat nests being notoriously infested with fleas.

Dr. L. W. SAMBON (London) gave a large amount of information about the old beliefs as to plague in animals. He thought that recent writers had forgotten the old ones. The cat and the dog were viewed as dangerous in reference to plague in the old days, and their destruction was advised as a preventive measure. He spoke of the bed-bug as well as the flea as a transmitter of plague.

Dr. A. J. CHALMERS (Colombo) referred to the experience of Ceylon, to which island large numbers of coolies from India were brought annually by ships. He thought that having regard to the large amount of immigrants from India infection might be likely to escape detection, and there were plenty of rats and fleas in Ceylon. Occasional cases of plague had occurred on coolie ships, but the disease had so far never gained a footing in Ceylon. He could hardly account for this immunity.

Dr. A. BALFOUR (Khartoum) said that there had not been any epidemics of plague in the Soudan, but whether this had relation to the hot climate he could not say. He spoke of iodoform as likely to be useful as a practical measure in keeping off fleas; this suggestion had been made by a German observer whose name he could not recall.

Mr. JAMES CANTLIE (London) believed that the seasonal variations in plague incidence had relation to temperature. He spoke of climatic bubo, which he regarded as a forerunner of plague, such cases occurring, in his experience, before a plague epidemic and also after it had subsided. The bacillus of climatic bubo, sometimes termed pestis minor, did not cause plague; but he believed it to be a stage in the development of the true plague bacillus. Step by step the bacillus of climatic bubo might increase in virulence until a plague epidemic was established.

Dr. G. F. PETRIE (London) said there had been no concurrent spread of rat plague in Manchuria during the recent human epidemic. There were plenty of opportunities for rats to acquire plague during the epidemic; for example, by gnawing human corpses, many of which remained unburied during the height of the outbreak. The origin of the Manchurian epidemic was obscure, but there was suspicion that the tarabagan, a species of marmot, which was known to be susceptible to plague, might have been an agent; the evidence implicating it was, however, indirect. The flea which lived upon the tarabagan bit human beings. This animal hibernated during the cold weather, and it was thought that perhaps the fleas also hibernated, and thus the infection persisted from one season to another.

Dr. MARTIN then replied upon the various points which had been raised. He did not regard the rise in temperature as inhibiting the plague bacillus. As regarded iodoform, he admitted it would keep off the fleas, but it would also, he suggested, keep away one's fellow men, the odour being so obnoxious to most people. He did not pretend to explain the mediæval epidemics on our present knowledge. The spread of the disease in the olden time was far more rapid than in the present day. He thought that if the characters of the plague bacillus were changed a little, this would produce a septicæmic form of plague as in the rat, and it

would then spread like wildfire. He had a conviction that the flea in biting man introduced into his blood the contents of its stomach, but this had not yet been demonstrated. The flea passed large quantities of fæces on the skin, and these often contained virulent plague bacilli, which, if rubbed into the punctures made by the flea, inoculated plague into man. There was as yet no proof that the flea's salivary gland was infected by the plague bacilli. He agreed with Dr. Sambon that dogs and cats might become sources of danger to man. He had no experience of climatic buboes, and there was no evidence that these were a manifestation of the attenuated virulence of plague bacilli.

The proceedings then terminated.

THE ANNUAL EXHIBITION.

(*Continued from p. 338.*)

II.—DRUGS.

THE display of drugs was full of interest, though there were fewer exhibits in this section than is usually the case. That fact, however, was not without its advantages, since a more complete and leisurely inspection could be made of the good things that were shown. Once again it was evident that the greatest care and skill are being exercised to obtain a high degree of purity of drug and to present it in a form best suited to the needs of the case. "Elegance," too, was a feature of the various pharmaceutical exhibits shown, and this department of the exhibition lent decided colour and decorative effect to the vista of stalls. In many instances there were some attractive preparations in the shape of stately columns of crystal growths or of specially prepared crystallised drugs. At the stall of the Hoffmann-la-Roche Chemical Works, of 7 and 8, Idol-lane, London, E.C., there was a fine display of alkaloids and chemicals. Crystalline crops of strychnine and crystalline specimens of guaiacol formed part of the decoration of the stall, but, in addition, there were digalen, a standardised preparation of digitalis, giving, it is said, the typical action of the drug without any unpleasant by-effects; omnopon, a soluble opium containing the total alkaloids of the drug; secacornin, a special standardised preparation of ergot; thigenol, an organic sulphur compound having antiseptic and antipruritic properties; and thiocol, a soluble and odourless guaiacol compound which has been used with good results in pulmonary diseases, one advantage of its use for children and delicate persons being that it is said not to produce gastric disturbances. The exhibit of Messrs. Burroughs, Wellcome, and Co., of Snow Hill Buildings, London, E.C., was most tastefully executed and had an additional attraction in the shape of a series of growing medicinal plants—nux vomica, digitalis, cardamoms, aconite, colocynth—brought from the botanical gardens in the firm's grounds at Dartford, where their fine chemical products are manufactured. The list included a series of tabloid and soloid products, Wellcome brand sera, vaccines, and tuberculins, and epinine, the synthetic substance possessing the suprarenal action in a high degree. Messrs. C. J. Hewlett and Son, Limited, of 35–42, Charlotte-street, London, E.C., showed a number of pharmaceutical preparations found to be of excellent service to the practitioner. Amongst them were a physiologically standardised ergot, a classic pepsin and bismuth mixture, "iodermiol," a non-staining and non-irritating preparation of iodine, and a series of concentrated liquors. Messrs. Southall Brothers and Barclay, Limited, of Lower Priory, Dalton-street, and Dale End, Birmingham, exhibited examples of their departmental work, laboratory equipments, chemical and crystallising laboratories (for iodine, potassium iodide, sodium sulphate, potassium citrate), standard tinctures from the galenical laboratory, palatable elixirs, glycerols and syrups, and so forth.

Messrs. A. and M. Zimmermann, of 3, Lloyd's-avenue, London, E.C., presented a large number of fine pharmaceutical products, including some organic silver preparations, organo-therapeutic preparations, and some recent remedies in the shape of Biebrich Scarlet R, which, it is said, promotes epitheliation of wound surfaces; amidoazotoluol, acting similarly but quicker; a new tuberculin (Rosenbach), an immune substance, "I.K.," and "nastin," employed by Professor Deycke in the treatment of leprosy. There were a good many objects worthy the attention of the medical man at the admirably set out stall of Messrs. Parke, Davis, and Co., of 50, Beak-street, Regent-street, London, W. The exhibits were striking in giving evidence of the advances made in pharmaceutical preparations and of a determination to meet the requirements of modern therapeutics. The exhibit included a series of serums and a complete list of the bacterial vaccines prepared under the supervision of Sir Almroth Wright in the laboratory of St. Mary's Hospital. There were also tuberculins for the ophthalmic and cutaneous diagnosis of tuberculosis, and a series of elegant standardised galenicals, as well as a pretty selection of "glaseptic" nebulisers and sprays.

Messrs. A. Wander, Limited, of 1 and 3, Leonard-street, London, E.C., in addition to bringing to the notice of the visitors their ovaltine, which, as our analytical columns have shown, is a combination of diastasic malt extract, milk, eggs (ovo-lecithin), exhibited a combination of malt extract with iron iodide, which is said to ensure the therapeutic action of iron and iodine without gastric disturbance or constipation, and to be free also from the effects known as "iodism." Messrs. Fassett and Johnson, of 86, Clerkenwell-road, London, E.C., exhibited for the Messrs. A. C. Barnes Company the silver proteid compound argyrol, which has been used successfully in ophthalmia and genito-urinary diseases; in addition, there was "ovo-ferrin," an iron proteid combination which is designed to avoid the undesirable effects of iron while securing its tonic action. There were excellent examples of fine pharmaceutical preparations and pure chemicals on the artistically arranged stall of Messrs. Brady and Martin, Limited, of Newcastle-upon-Tyne, who devote special care to the purity of therapeutic agents. There were an array, also, of capsules, pills, and tablets, and a series of physiologically, as well as chemically, standardised tinctures. There were some good old and new friends in the exhibit of Messrs. Oppenheimer, Son, and Co., Limited, of 179, Queen Victoria-street, London, E.C. Their "aeriser" is well known as an atomiser which "renders fluid like smoke"; the powder pill, called a "pulverette," has also been before the profession for some time—the drug in powder form is enclosed in a kind of eggshell made of sugar coating. "Grindeline" is a comparatively new preparation for asthma which is said not to induce a "drug habit"; it contains amongst other things grindelia with euphorbia, trinitrin, and potassium iodide. The exhibit included also a new preparation of bismuth and pepsin ("liq. gastro-rube"), mercury atoxylate cream, and an oxygen generator and "oxinhalator." Messrs. W. A. Wharram, Limited, of 115 and 117, Vicar-lane, Leeds, showed a series of elegant pharmaceutical preparations chiefly in liquid form. Such were a liq. bismuth co. c. pepsin, a linctus heroin hydrochlor., a liquor santali comp., and a liquor antisepticus, with thymol, eucalyptol, boric and benzoic acids as agreeable antiseptic agents. The exhibit included a neutral syrup of the hypophosphites and an iodine ointment, odourless and producing no stain. Lymphoid compound for oral administration and lymph serum for hypodermic use formed the subject of the exhibit of the British Organo-therapy Co., Limited, of Carlton House, Lower Regent-street, London, S.W. The claim urged in favour of these products is that they are valuable in the treatment of nervous and mental conditions arising from cell degeneration, disturbed metabolism, and auto-intoxication. Close by the Denver Chemical Manufacturing Company, of 41, St. Ann's-road, Bow, London, E., exhibited specimens of their anti-phlogistine, a scientific cataplasm which has been found of signal service in the relief of pain and in the reduction of inflammation and congestion. Miol (The Miol Manufacturing Company, Limited, 82, Southwark Bridge-road, London, S.E.) appears to be holding its own as a special food in debilitated conditions. It is composed, as has been shown in our analytical columns, of active malt with olive oil, iodine, and phosphorus, and is suggested as a pleasant and effective substitute for cod-liver oil.

Glycerophosphate preparations were given considerable prominence at the stall of Messrs. Huxley's Pharmaceutical Products Company, of 59, Dingwall-road, Croydon. Thus there was a non-saccharine syrup of acid glycerophosphates, a syrup of glycerophosphates with formates, with hæmoglobin, pepsin, red bone-marrow extract, and so on. The exhibit included a menthol and wintergreen cream, and sal-antisepticus (a powder containing well-known antiseptics). It is impossible in the space at our

disposal to enumerate all the fine pharmaceutical products exhibited by Messrs. Wyleys, Limited, of Coventry. There were some excellent liquores, tincturæ, and misturæ submitted for inspection, and many excellent forms of administration were shown, as, for example, medicated pastels, perles, and compressed tropels. We have already reviewed some of the surgical exhibits of Messrs. Reynolds and Branson of Leeds, but they are wholesale chemists as well as surgical instrument-makers, and their exhibit included some elegant drugs and pharmaceutical preparations, amongst which were a preparation of bismuth and pepsin, physiologically proved preparations of digitalis, ergot, Indian hemp, squill and strophanthus, suppositories of bismuth subgallate, and a series of admirable unguents. The Bayer Co., Limited, of 19, St. Dunstan's-hill, London, E.C., had an imposing show of many well-known pharmaceutical products introduced by them. Amongst new ones were adalin, a derivative of urea combined with bromine, described as a safe and efficient hypnotic; ferro-sajodin, a combination of iron with the well-known organic iodine compound, prepared for use in scrofula and rickets so as not to disturb the digestion; gynoval, a valerian derivative; sophol, a new organic silver compound for use in ophthalmological practice; spirosal, an external application for rheumatism; and thyresol, an advance on sandal-wood oil. The Charles H. Phillips Chemical Company, of 14, Henrietta-street, Covent Garden, London, W.C., exhibited two products, a milk of magnesia and a phospho-muriate of iron compound. The former is a uniform "milk" containing a specially prepared hydrate of magnesia, which serves as an excellent antacid; the latter contains the phosphates of potash, magnesia, lime, and iron, with the hydrochloride of quinine, a formula which indicates its value as a general tonic. Amongst the pharmaceutical preparations exhibited by Messrs. James Woolley, Sons, and Co., Limited, of Manchester, were a useful sodium phenate solution, a tablet containing the same agent plus red gum and eucalyptus oil, suggested for use in post-nasal catarrh and relaxed throat and in certain gastric troubles; a liquor thymol. alkalinus, a hæmoglobin capsule, and a series of soluble gelatin capsules. Synthetics were in evidence at the stall of Messrs. Zimmer and Co. (Frankfort-on-the-Main), who were represented by Messrs. Widenmann, Broicher, and Co., of 33, Lime-street, London, E.C. Amongst these may be mentioned allosan, a derivative of santalol, which has been, we understand, efficient in the treatment of gonorrhœa; euquinine, or ethyl-carbonate of quinine, which is tasteless, its action being physiologically that of quinine, but without "quinism"; validol (menthol and valerianic acid), a sedative and preventive, it is stated, of sea-sickness; and validol camphorate for allaying pain in dental decay.

The chief substance exhibited by the Saccharin Corporation, Limited, of 10, Arthur-street West, London, E.C., was novocain, described as "the non-irritant local anæsthetic." There is considerable evidence in its favour compared with cocaine, and its compatibility with the active principle of the suprarenal gland, as well as its complete solubility in water, are unquestionable advantages. There was also exhibited at this stall pergenol, a solid compound of hydrogen peroxide and borax, dissolving in water and yielding at once a solution of peroxide of hydrogen and boric acid, a powerful disinfectant and antiseptic fluid, the advantages of which in medical practice have already been described in our analytical columns.

It is probable, judging from the obvious attention which the visitors gave to the pharmaceutical products displayed, that this section proved to be next in interest to the surgical exhibits.

(To be continued.)

EPSOM COLLEGE: FOUNDER'S DAY.

THE annual distribution of prizes took place at Epsom College on Founder's Day, July 29th, in the presence of a large gathering of people, including Sir William Church, Sir Henry Morris, Sir Shirley Murphy, Dr. Norman Moore, Dr. Frederick Taylor, Dr. F. Needham, Mr. G. H. Makins, Dr. C. Caldecott, Mr. Purnell Purnell, Mr. Stanley Boyd, Dr. F. de Havilland Hall, and several distinguished laymen.

After service in the College Chapel the counting of votes for the Hodgkin prize took place. This prize is given in alternate years with the Wakley prize, and consists of an illuminated certificate and a cheque for £14, awarded on the recommendation of the masters and by the votes of the schoolboys. It was adjudged this year to G. N. Wrightson by a very large majority.

The visitors then inspected the handsome memorial tablet recently erected in the chapel to commemorate the long and valued services rendered to the College by the late Sir Constantine Holman. The tablet is made of alabaster and has two upper corner panels carved in slight relief on a gold mosaic ground. The cross at the top and the band between the narrow moulding are both of green Irish marble. The following is the inscription:—

To the Glory of God and in Memory of
Sir CONSTANTINE HOLMAN, M.D.,
Who devoted many years of untiring care to the welfare of this College, of which he was ever a steadfast friend and benefactor.
VICE-PRESIDENT OF THE COLLEGE, 1892-1910.
TREASURER, 1887-1906.
Born, 23rd October, 1829. Died, 18th August, 1910.

The headmaster, the Rev. T. N. H. SMITH-PEARSE, gave the usual report of the school work, and referred to the loss sustained in the deaths of Sir Constantine Holman and Mr. Hugh E. Vardon, the latter of whom had made provision for the "Hugh Vardon" scholarships. He spoke of the services rendered to public schools by Sir Henry Morris in connexion with the recent decision of the General Medical Council that public schools could be recognised as places at which the preliminary sciences might be studied, the time thus given being counted towards the first year of the medical curriculum. The well-equipped laboratories of the College had attracted much attention from visiting members of the General Medical Council.

Dr. NORMAN MOORE, who distributed the prizes, said that all the 11 great medical schools of London had boys from that College. He referred in succession to various additions to knowledge made by the different medical schools of London, and gave a very interesting account of them. A colleague of Sir Henry Morris, Sir Charles Bell, had made the second greatest discovery in physiology—viz., the existence of separate nerves for motion and sensation. He particularly dwelt on St. Bartholomew's, which was connected with our great foundation of liberty, for three persons of the foundation had been among those who obtained Magna Charta for us. The work of Epsom College, he said, was divided, like the work of most public schools, into two halves of study—literature and science. He discussed the advantages of a literary training, and impressed on his hearers the delights which literature, when it came to form part of their minds, would confer throughout life. He made a point of the appeasing influence of literature, showing how the old-time hostility between Highlanders and Lowlanders in Scotland had been dissipated as a result of the literature of Sir Walter Scott. As to science, he spoke of its unifying influence on mankind, and instanced among other things Kitasato's work. He urged his hearers to be followers of both literature and science, and contemners of neither.

Sir HENRY MORRIS proposed a vote of thanks to Dr. Norman Moore, and emphasised the connexion already pointed out between such a school as Epsom and medicine, the association between medicine and the hospitals, and of these with the development of science.

In addition to the ordinary school prizes certificates were presented to the members of the Officers' Training Corps, Cadet Officer Crimby receiving the King's Coronation medal.

Among pupils of the school who have been distinguished in various medical fields since last Founder's Day are R. A. F. Eminson and W. R. Wilson, who took respectively second- and third-class honours at the Natural Sciences Tripos at Cambridge; Captain H. C. Winckworth, R.A.M.C., created Chevalier of the Crown of Italy; J. A. B. Hicks, appointed assistant pathologist and curator of Westminster Hospital Museum; C. W. Morris, appointed house surgeon at University College Hospital; B. F. Eminson, who gained the William Travers prizes at Charing Cross Hospital for medicine, midwifery, and public health; B. C. Maybury, appointed casualty officer and resident anæsthetist at St. Thomas's Hospital; and H. G. Dodd, passed Second M.B. Durham with honours.

THE LANCET.

LONDON: SATURDAY, AUGUST 5, 1911.

The National Insurance Bill.

THE House of Commons during the week has been debating in committee what must be to our readers the most critical parts of the National Insurance Bill now that Clause 8 of this intricate and far-reaching measure has been temporarily settled. Clause 12 dealt with the provisions to be made in the case of contributors who are inmates of institutions such as workhouses or asylums which are supported by public authorities, or such as hospitals and sanatoriums supported perhaps by charitable and perhaps by public funds. Clause 13 dealt with the benefits to be administered by approved societies or Local Health Committees, and under it the whole question of club medical practice came in for discussion. Clause 14 dealt with the administration of medical benefits.

The position and future of the voluntary hospitals under the Bill was the subject of a very earnest debate on July 31st when Clause 12 first came up for discussion. There were those, on the one hand, who argued that the Bill would greatly increase the work thrown on the hospitals, while at the same time the financial position of these charities would be seriously hampered. Mr. AUSTEN CHAMBERLAIN, taking this view and speaking for 44 hospitals in the midland counties, maintained that the financial loss that these institutions would incur would be in no case under 50 per cent., and in some instances would reach 75, 80, or even 90 per cent. He emphasised the detriment to the public that would result from any such paralysis of the training institutions in medicine and surgery, and suggested various ways in which this difficulty could be met. Mr. LLOYD GEORGE considered that the fears as to the adverse effect on hospitals were exaggerated, and that the lessening of work and the new sources of income that would be tapped had alike been left out of consideration. He argued further that there was no ground to suppose that the contributions of either employers or employed would be materially lessened. Mr. AUSTEN CHAMBERLAIN, however, moved an amendment providing that any payment under the Act shall, if the patient be an inmate or patient of a hospital or institution supported wholly or partly by voluntary subscriptions, be divided between that hospital or institution and his dependents (if any) in such proportions as the Local Health Committee may determine. Dr. CHRISTOPHER ADDISON, speaking on this amendment, predicted that soon after the scheme was established there would be a great addition to the work of the hospitals. This would necessitate the organising of a proper standard between the hospitals and the insurance scheme and some organisation maintained, through the Local Health Committee was the proper way to deal with this hospital question. The sick fund was not the right fund out of which to take the money. This point of view was strongly supported by several members, and Mr. CHAMBERLAIN'S amendment was withdrawn. An amendment by Mr. LLOYD GEORGE, however, was carried to enable an agreement to be entered into with a charitable institution by an inmate who has no dependents, whereby his sick benefit may be paid in whole or in part towards his maintenance in the hospital. The amendment further provides that in the case of a married woman entitled to sick benefit in addition to maternity benefit, no part of the maternity benefit shall be paid to the dependents, the whole accruing to the hospital for her maintenance. Clause 12 was then agreed to, the debate in the House well reflecting the diverse views and necessary uncertainties of all who know the circumstances of hospital administration. No one can say under this clause whether the hospital incomes from charity will so seriously decline that the State, in the character of an increasing contributor, may not ask for some amount of control that would alter at once the existing conditions of scientific work and medical education.

The consideration of Clause 13 produced a debate that will be for many years memorable in the medical profession. The main lines of the discussion can be followed in the summary of our Parliamentary correspondent, while the daily press has done full justice to its enormous importance. The clause, as we have said, dealt with the whole matter of club practice, inasmuch as under it fell the question of how far the administration of medical benefits should remain with the various existing medical aid associations and how far with the Local Health Committees created by the Bill. In a simple amendment Dr. ADDISON proposed to transfer the whole of the administration of medical benefits from the various approved societies to the Local Health Committees, and supported the strongly manifested medical views in a convincing speech. He demonstrated quietly but effectively the public danger of permitting the management of what amounts to a national health service to remain under the control of organisations of varying ideals and different standards; while once again, and from each part of the House, Members heard the difficulties under which club practice has for so long been carried on, its inefficiencies, and its injustices to the medical profession. The Chancellor of the Exchequer, who allowed that he was personally in favour of the amendment, left its fate to the opinion of the House, when by the remarkable vote of 387 to 15 the administration of medical benefits under the Bill was transferred to the Local Health Committees. This may be regarded as a triumph.

Around Clause 14 the principal fight was now centred, for it will be remembered that Mr. LLOYD GEORGE definitely promised, during the debate on Clause 8, that if anything during the consideration by the Committee of Clause 14 should make it necessary—that is to say, that if it was found out of order or inconvenient to discuss such matters as wage-limit on Clause 14—he would undertake to have Clause 8 re-committed. In this way Clause 14 became

of vital interest to the medical profession, as being concerned both with the definition and distribution of medical benefits. We may take it for granted that every one of our readers knows, at any rate, the general bearings of the clause as it stood in the Bill. There were down no less than 14 pages of amendments to this one clause. Three were, however, of outstanding importance. The Chancellor of the Exchequer had put down an amendment to provide that the Local Health Committee should be able to make arrangements with duly qualified medical practitioners for insured persons to receive attendance and treatment "in accordance with regulations made by the Insurance Commissioners," and had set out at considerable length the provisions of these regulations. In this manner the Chancellor of the Exchequer proposed to provide a fair distribution of insured patients among the practitioners willing to attend and treat them, while the right on the part of an insured person was also recognised to select from a properly prepared panel the practitioner by whom he wishes to be attended. These proposals of the Chancellor, it may be remembered, were foreshadowed in the statement which he originally made to ourselves. Dr. ADDISON had put down an amendment providing that, under the regulations made by the Insurance Commissioners, authority should be given to the Local Health Committee administering medical benefits to arrange that persons whose incomes exceeded the limit fixed by the Insurance Commissioners should make their own arrangements for receiving medical attendance and treatment, the Committee contributing from the funds out of which medical benefit is payable towards the cost of such medical attendance and treatment. Dr. ADDISON'S amendment therefore touched upon the difficult subject of wage-limit in a judicious and tentative manner. More in keeping with the views of many general practitioners was the amendment to the same clause of Sir PHILIP MAGNUS, which provided that no insured person should be entitled to medical benefit if his average income from all sources in the calendar year preceding the date at which he became entitled to sickness benefit exceeded the sum of £104. Our readers know already from the long and accurate accounts in the daily press what was the fate of these amendments. In spite of some able arguments from its proposer and from Sir ROBERT FINLAY, Sir ALFRED CRIPPS, Sir HENRY CRAIK, and others, Sir PHILIP MAGNUS'S amendment for the fixation at £104 of the maximum income of persons to receive medical benefits under the Bill failed to secure support. The amendments of Mr. LLOYD GEORGE and Dr. ADDISON were accepted, and under these the Local Health Committees will be the arbitrators with regard to the payment of fees for medical services by insured persons able to do so. The clause as amended represents, we believe, the general expectation of the medical profession.

METROPOLITAN HOSPITAL SUNDAY FUND.—The Lord Mayor presided over a meeting of the council of this Fund which was held on August 1st at the Mansion House to receive the report of the Committee of Distribution. It was recommended that £56,500 should be distributed among 166 hospitals, 59 dispensaries, and 32 nursing associations.

Annotations.

"Ne quid nimis."

THE POST OF CHIEF MEDICAL OFFICER TO THE LONDON COUNTY COUNCIL.

WE announced last week with much regret the impending retirement of Sir Shirley F. Murphy, chief medical officer to the London County Council, consequent on the reorganisation of public health administration of the Council. On August 1st it was resolved by the Council "that applications be invited by public advertisement from qualified persons whose age will not exceed 50 years on Jan. 1st, 1912, for the position of medical officer of health of the County of London and school medical officer for the County of London, at a commencing salary of £1250 a year; and that members of the staff be not precluded from making applications for the position."

CANCER RESEARCH.

THE investigation of the problems of cancer proceeds apace, and every year is adding to our knowledge of the facts connected with the disease. It is true that we have not yet answered the two chief questions, its cause and its cure, but our knowledge is increasing, and we have little doubt that before long it will receive still more important additions. In the last issue of THE LANCET was printed the ninth annual report of the Imperial Cancer Research Fund, and from that it will be seen that material additions have been made to our knowledge of the subject. The Fund is peculiarly happy in having the coöperation of the Registrar-General in obtaining statistics of the incidence of cancer, for societies for the investigation of cancer in other countries have so far depended for their statistics on figures collected by the voluntary assistance of the medical profession, and this leads to much unnecessary work. One important point that statistics have brought out is that the increase of cancer during the last decade is referable to certain anatomical regions and not to others; thus in males the increase is almost confined to the alimentary canal, while in females it mainly affects the same system, although the breast also suffers. Much has been done to investigate the relation between the tumour and the animal in which it appears, and it seems to be shown that it is not any special peculiarity of soil which favours the growth of a cancer, for transplantable tumours grow as well in normal animals as in those in which they first appeared; yet a spontaneous tumour can hardly ever be implanted into an animal in which there has arisen a spontaneous tumour. As to treatment, experiments have proved that it is to some extent possible to modify the growth of propagated cancer in animals, but it has not yet been found possible to arrest the growth of spontaneously arising tumours, and it is at least doubtful whether any real progress is to be made along these lines. Thus, this report, though not as yet affording us any clear indication of a method of preventing or destroying cancer, has distinctly advanced our knowledge, while it stimulates our hope of more direct results. In the present number of THE LANCET appears a paper by Mr. C. J. Bond of Leicester on the theory of cancer. He discusses fully the mode in which a cancer arises, and he adduces evidence which appears to him to support the conclusion that the complex cell changes which we associate with cancer have been built up by variational changes from the normal type, and that one of the stages passed through is represented by the various forms of benign growth. The formation of a tumour he regards as an adaptive response on the part of individual cells or cell-groups to

environmental change of three kinds—either a change in the stimuli which reach the cell from the outside world, or a change in nutrition, or in the activities in the other cells which compose the organism. The striking condition of the skin of the chest wall which is known by the name of "cancer en cuirasse," and which follows carcinoma of the breast, has always received much attention since it was described and named by Velpeau in 1838, though indeed it had been noticed by Howard in 1792. This condition has long been considered to be due to a malignant infiltration of the lymphatics of the skin; but lately this view has been challenged by Mr. W. Sampson Handley, who has done so much to advance our views of the mode of spread of malignant disease. Mr. Handley considers it to be an œdematous infiltration of the tissues due to lymphatic blocking. Sir George T. Beatson has submitted to careful histological examination the skin of a patient who was afflicted with this form of malignant disease, and has described the case very fully in another column. He is convinced by what he found that the ordinary view is correct and that the condition is certainly due to the spread of the malignant growth along the superficial lymphatics. It is possible that both views are correct and that the "cancer en cuirasse" has a different pathology in different cases, but it is certainly a matter that should be settled, for though the disease is not common it cannot be described as very rare. The problems of cancer are of vast importance, and though we are not in view of the end there can be no doubt that we are making progress. The difficulty lies in the complexity of the matter. A letter from Mr. Harry Lyle and a brief record of a case of recurrent melanotic sarcoma by Dr. Charles H. Lilley indicate other lines of observation to be followed. Mr. Lyle considers that the part played by simple inflammation on the prevalence of malignant disease is not sufficiently recognised, while Dr. Lilley's clinical note warns us of the long interval over which recurrency may take place. In every direction—clinical, biological, and statistical—there is great work to be done, and there is certainly a prospect ahead that the research of those who do it will receive better attention.

SUMMER CLOTHING FOR MEN.

DURING the long spell of magnificent weather that has been such a notable feature of this Coronation year the question of how to dress comfortably must often have perplexed the professional man confined to city life, and therefore to some extent forced to observe the conventions. Of late years there has certainly been a far less rigid adherence to these conventions than, say, 20 or 30 years ago; but the legal and medical professions, at any rate, have been on the whole conservative in this respect. With regard to headgear, the ordinary silk hat of the town dweller has long been criticised; but it must be admitted that in spite of many attempts to displace it in popular favour it remains the *sine quâ non* for certain society functions, though not now so indispensable for many others where a short time ago it was quite compulsory. We do not understand why the white tall hat has fallen out of use; it was lighter to wear, cooler to look at, and, so long as there was no black band to suggest that the wearer was in mourning for the last remnants of his respectability, its appearance was cheerful. Straw hats, that now form so large a proportion of the summer headgear of our town population, are certainly cool and light; the soft panama variety looks more comfortable, but not only is it much more expensive, but from a medical point of view it has a drawback. Whatever type of hat is worn the lining should be soft and elastic, so that there is no constriction anywhere round the brow; yet the panama offers so large a surface of attack for sudden wind that it must be tight to the forehead. The air-space above the head should be ventilated. Air itself is a bad conductor of heat, and if a deep layer of air is interposed between the head and the head covering, this forms the best protection against the effects of sun, provided, of course, that the air layer is kept cool by free ventilation. Although the tall hat to some extent retains its vogue, the double-breasted frock-coat has almost disappeared for daily use; but we still seem to cling to funereal black as the appropriate hue for city life. Our climate is so variable that we cannot always assume that a fine warm morning will be followed by a hot day; therefore we cannot always at the beginning of the day dress appropriately for the ensuing eight hours or so. Woollen stuff for material, and a loose fit, will secure comfort, and protection from extremes both of heat and cold. Light coloured garments are naturally cooler than dark ones, as they reflect instead of absorb the sun's rays; but a permeable texture is of much more importance than colour; it is necessary for health and comfort that free passage should be allowed for evaporation from the skin, inasmuch as this is the most effective physiological means of cooling the body. Dwellers in tropical countries generally wear white cotton clothing, very light in texture, being careful, however, to protect the head from the sun's direct rays by some form of turban, and the abdomen from chill by several folds of material, forming a cummerbund. With our variable climate we must be cautious, even in the hottest weather, how far we imitate the habits of people whose weather is so settled one way or another as to afford no topic of conversation. The male garments of the present day, save where a ceremonial occasion or a professional convention alters the circumstances, are loose in texture, not tightly fitting, and not necessarily dark in colour. They are hygienically reasonable and practically well adapted for the requirements of ordinary life, and we rejoice in the emancipation from actual discomfort that is implied in them for many of our readers. On the whole, it seems to us that the general tendency of modern fashions in masculine dress is towards reasonableness and comfort; while with regard to women, the increase in active exercise on their part that is now almost universal, and the spread of liberal views in education, have wrought a great change in all ranks of society.

THE OXFORD OPHTHALMOLOGICAL CONGRESS 1911

THE Oxford Ophthalmological Congress, which assembled at Keble College, Oxford, on July 13th last, was well attended, especially by members from the other side of the Atlantic. The business session was opened by an address of welcome by the Master of the Congress, Mr. Robert W. Doyne, reader in ophthalmology in the University of Oxford. He was followed by Professor Arthur Thomson, who dealt with the anatomy and physiology of the parts about the so-called "filtration angle" of the eye. His remarks were illustrated by a series of beautiful lantern slides. Dr. Lieven of Aachen then spoke on salvarsan, and he was followed by Major R. H. Elliot, I.M.S., of the Government Ophthalmic Hospital at Madras, who described lucidly his operation for trephining the sclera in cases of glaucoma. He has performed the operation on 403 eyes, and he analysed the results in 66 of the patients who had returned for observation. Major Elliot's very practical communication was well received by a crowded audience. The afternoon was devoted to the witnessing of operations performed by Mr. Charles Higgens of London and Dr. S. Lewis Ziegler of Philadelphia. The opportunity was also taken of inspecting a number of interesting eye cases assembled by the staff of the Oxford Eye Hospital. On the following day addresses dealing with subjects of interest

to ophthalmic surgeons were delivered by Professor Francis Gotch, Dr. StClair Thomson, and Dr. Francis Low. In the department of physiology, microscopical specimens, new instruments, ophthalmoscopic drawings, novel operations, and so forth were shown or demonstrated by Mr. H. Herbert, Major G. H. Fink, Dr. F. W. Edridge-Green, Dr. Wiston Baker, Dr. Thomson Henderson, Mr. R. Granville Waddy, Dr. Wendell Reber, Mr. P. E. H. Adams, Mr. R. J. Coulter, Mr. A. Bernard Cridland, Dr. T. Harrison Butler, Dr. Alexander G. Gibson, Mr. H. G. Armstrong, Dr. R. M. Truter, Mr. R. W. Doyne, Mr. Sydney Stephenson, and others. In addition to all this, many firms of repute showed the latest optical and surgical appliances. The social side of the Congress (always a feature at these meetings) was represented by the official dinner held in Keble Hall on July 13th, the chair being taken by Sir William Osler. The chief guests included the Vice-Chancellor of the University of Oxford and Dr. W. Lock, the warden of Keble College. Other affairs included a garden party at Balliol College, a visit to the Clarendon Press, and a smoking concert at Keble College.

THE SEA AND ITS VOTARIES.

DERIVED perhaps from their insular instincts there is a conviction in the minds of probably most British people that in matters regarding the recuperation of health there is nothing like the sea. "A blow from the briny" is a very common recommendation in slackness, and is meant to suggest that sea air is salutary. In not a few cases that is a delusion. It is true that as a rule there is nothing to be said against the quality of sea air; it is cool, pure, and clean, its supply is unlimited and ever fresh, and yet there may be found by medical men a reason for warning their patients about the drawbacks of the environment. The amusements offered at the seaside may be so varied compared with those of a quiet country life that the temptations of fishing, bathing, sailing, and water sports in general are difficult to resist, even although it is the visitor's common experience time after time that the sea does not exactly suit his general health. "I love the sea, but the sea somehow does not suit me," are the words with which such an individual sums up his case. It is a mischievous idea in the layman's mind that the remedy for all weak states of health is necessarily sea air. It is not always that the individual seeking strength can respond to the powerful and exciting stimulus of the bracing sea air; the digestive, secretory, circulatory, and eliminatory systems may be goaded to an energy of which they are incapable, by reason of a general debilitated condition; they are not able to do their work without exhaustion, and the last state of that man may be worse than the first. When sea air disagrees with the temperament digestive disturbances arise, and if the excretory functions are not in good going order, as in the case of the so-called bilious individuals and plethoric persons, headaches, giddiness, and a train of symptoms commonly summed up as "biliousness" makes an appearance. As a rule, the effect upon such cases of the less stimulating country air is magical. When that is so, it means that the great human machine and its complexes gain vigour best by repose. When strength has been restored in this way the medicine may be changed and the tonic air of the sea be prescribed with the greatest advantage. The matter is of some moment to the man who finds that a seaside holiday is a strain upon his means, for if sea air does not suit his particular needs he is not only throwing his hard-earned money away but receiving, it is possible, a set-back to his health. He may, however, justify his adherence to the seaside on the ground that it does his wife and children good—and he will be admired for that view—but in such a case the indications for him, at all events, are first the country or even a stay at home, and then the sea or mountain air. There can be no more satisfactory formula for the restoration of the hard-worked person than first a soothing, restful environment and then a tonic one. To plunge straight into the tonic, invigorating air of the seaside is an irrational procedure for many "run-down" cases. A stimulus given when there can be no response is a debit on what strength is left. It is no axiom, therefore, that the sea spells health.

RUPTURE OF THE SUPRASPINATUS TENDON.

IN the *Boston Medical and Surgical Journal* Dr. E. A. Codman has reported two cases of a very rare injury—complete rupture of the tendon of the supraspinatus. A healthy woman, aged 52 years, was referred to him by her medical attendant on March 7th, 1909. On Oct. 3rd, 1908, while hanging clothes on a line, she endeavoured to toss over a heavy blanket and felt something snap in her shoulder. She felt an intense pain and the arm fell and hung by her side. Her medical attendant found no thickening or ecchymosis and radiography was negative. Since then she had been unable to abduct the arm and suffered pain, especially at night. The symptoms generally were such as Dr. Codman has described in subacromial bursitis, but the following points were different. There was little atrophy of the deltoid, and it even appeared to be hypertrophied in consequence of apparent swelling of the joint beneath. Under the fibres of the deltoid, beneath the acromion, and over the joint, there was distinct deep fluctuation as if the whole bursa was full of fluid. Though the patient could not start abduction, when the arm was passively abducted to about 140° she could by a strong contraction of the deltoid for an instant prevent the arm from falling, but the slightest downward pressure caused it to drop to the side. External rotation was about one-half of normal. An incision was made between the fibres of the deltoid, and the roof of the bursa was found thickened with granulation-like bodies. On opening the bursa about half an ounce of straw-coloured fluid escaped. The floor was found to communicate with the joint, because practically the whole supraspinatus was torn from its insertion and retracted inwards. By holding the bursa wide open, pulling down the arm, and raising the elbow from the table the retracted end of the supraspinatus could be seen. This was caught with a tenaculum and pulled down enough to suture it with four heavy silk threads to the portion attached to the tuberosity. After the operation the arm ached at times, but she gradually recovered complete use of it. In March, 1911, function was perfect, and the only sign was that the deltoid was unusually prominent in consequence of fluid in the bursa. In the second case, an ostler, aged 40 years, who had always been strong, was seen on Dec. 21st, 1910. About three and a half months previously, whilst tightening the girth of a horse, he felt something give way in his shoulder and fell. He immediately lost power in his arm, but managed to complete saddling without raising it. His medical attendant thought he felt slight crepitus, but a skiagraph was negative. On examination it was first thought that he was suffering from the adherent type of subacromial bursitis, but the same conditions were found as in the previous case, and also there was a distinct depression just above the tuberosity of the humerus. Rupture of the tendon of the supraspinatus was diagnosed. On operation straw-coloured fluid escaped from the bursa, which communicated with the joint. The supraspinatus had retracted so far that it could not be seen, and with some difficulty the tendon was caught with a tenaculum and pulled forward. It was sutured to the tuberosity with

heavy silk prepared with paraffin. Abduction was not allowed for three weeks, and then the patient began to use the arm. On March 25th, 1911, he could easily place his hand on the top of his head, but full abduction was still weak. The function of the supraspinatus was as good as in the previous case at the same period after operation. In only one other case has Dr. Codman diagnosed complete rupture of the supraspinatus. The patient, a powerful man, who declined operation, four years after the injury was unable to start abduction. Partial rupture of the tendon of the supraspinatus Dr. Codman regards as common. He has no difficulty in finding it in the dissecting room. It is usually not more than half or a quarter of an inch in breadth, and does not interfere much with the function of the arm. Such ruptures are best considered with the subacromial bursitis, which they cause. They are beneath the serous base of the bursa, which may or may not be torn through. If straw-coloured joint fluid is found on opening the bursa careful search will usually demonstrate a small opening into the joint at the point of rupture. Usually suture is unnecessary, and healing takes place if the inflamed portion of bursa over the rupture is clipped away with scissors.

SUMMER HEALTH PROPAGANDA IN AMERICA.

THE Chicago Department of Health is essentially an educational department. It teaches what is too often neglected in schools, and, what is equally necessary, it attempts to teach those who are too old to go to school. Every week the department issues and sends free of charge to "those who should be benefited by it" a small bulletin popularly written to disseminate the advice and information the sanitary authorities have to give. At the present time this consists of practical suggestions for coping with the heat, and, above all, for preventing the diseases that are so fatal among infants and children during the summer months. Then a big poster has been placarded with illustrations showing the typhoid dangers of summer resorts. In one corner the railway platform and departing train is depicted. Then comes the country road with manure carts and motor-cars, and the dirty farmyard where children are drinking from a pump close to the manure heap. Further on there is a river with a water intake and people bathing close to a sewer outfall. While yet further under the shade of trees a picnic party is enjoying a meal in the open air, but flies are coming over the food straight from a privy that is close at hand. Finally, what is called Summertown Hotel derives its water-supply from a well dug at a lower level than the graves of the cemetery that is close by. In August and September there is generally an increase of typhoid fever at Chicago. This coincides with the return from such summer resorts of many inhabitants. They are therefore warned not to go where there are shallow wells near barn-yards or where the water-supply comes from a river that receives sewage. When there is reason to suspect the water it should be boiled and a sample sent to Chicago for analysis. Automobile parties should carry their own water-supply with them. There are special bottles and other contrivances that will keep the water cool. Milk should be pasteurised and the farms whence it comes visited, and not patronised if they are not clean. Any place swarming with flies must be avoided; flies are clear evidence that there is filth in the neighbourhood. "Clean, safe food cannot be served in a dining-room in which there are swarms of flies." Chicago, with its good water-supply and the care taken in watching over the milk-supply, is much safer than summer resorts that have sanitary defects. But there are some summer resorts where the drinking water is pure, the bathing water clean, the scavenging so well done that there are hardly any flies. These places should be encouraged by extensive patronage. The newest development in Chicago teaching is the efforts made to make the public understand the danger of house-flies. "Filth *plus* flies and fingers equals fever" is a new sort of arithmetic now taught. Newspaper wrappers are printed bearing the picture of a fly and the inscription "Kill that fly," when the Americanism "swat" is not used. Then we have maxims such as "Don't forget that one fly swatted now will save a million swats two months hence." Or else the authorities resort to such rhyme as—

> "This is our summer battle-cry,
> Muzzle the dog; swat the fly,"

followed by the warning, "Where flies multiply there the babies die." This is all good work, particularly as the householder is told how to avoid the flies denounced as so dangerous. A little common kerosene mixed with crude carbolic acid, 1 per cent. of acid, or 1 ounce of acid to a quart of kerosene sprayed upon garbage will prevent flies coming and kill eggs and larvæ. Manure that cannot be covered over should be treated with one pound of sulphate of iron in a gallon of water. It does not affect the value of the manure, but kills the maggots. Still, the best of all precautions is the prompt removal of garbage or manure.

THE library and offices of the Royal Society of Medicine are closed until Sept. 1st.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—An ordinary meeting of the Council was held on July 27th, Sir Henry Butlin, the President, being in the chair. It was resolved to grant Diplomas of Membership to 95 successful candidates, and it was also resolved to grant, in conjunction with the Royal College of Physicians of London, Diplomas in Public Health to 20 successful candidates. Newnham College was added to the list of institutions recognised by the Examining Board in England for instruction in chemistry, biology, and physics. A letter to the President from Dr. Edmund Hobhouse was read, asking the President, on behalf of the medical and surgical staff of the Sussex County Hospital, to accept for the College a complete skeleton of mollities ossium and such other specimens as should be considered desirable. The best thanks of the Council were voted to the staff of the Sussex County Hospital for their gifts.

THE "ENSEIGNEMENT MEDICO-MUTUEL INTERNATIONAL."—The session of this body, generally known as the "E.M.I.," will be held in Scandinavia from August 12th to 30th, and, thanks to the efforts of Professors Ehlers (Copenhagen), Johannessen (Christiania), and Wanrinski (Stockholm), promises an interesting programme. The following visits have been arranged:—At Copenhagen: Rigs Hospital, the Modern Hospital of Mont l'Evêque (1300 beds), the Finsen Institute, the Institute of Serotherapy, the communal establishments of hygiene, schools, sewerage plants, the modern municipal dairy (to be visited at 2 P.M., when in active work), a Danish gymnastic course for women, and a conference on medical education in Denmark. At Christiania: the State Hospital, the Modern Communal Hospital, the Dikemark Insane Asylum, the municipal school, the city sanitary institutions, and the climatic sanatoriums. At Stockholm: the special hospital for contagious diseases, the Swedish Hospital for the Care of Children, the primary school, the new abattoir, the Bureau of Hygiene, the public baths, the water-supply, and the new sanatorium for tuberculosis. Other interesting topics for study in applied hygiene will be the schools for the crippled, physicotherapy, alcoholism, and leprosy at Bergen; the working of the refuse incinerator and the Hospital for Tropical Diseases at Hamburg; the Institute and the Museum of Hygiene at Berlin. Finally, a visit will be paid at the close of the session to the International Exhibition of Hygiene at Dresden. For further information application should be made, enclosing an international postage coupon, to the headquarters of the "E.M.I.," 12, Rue François Millet, Paris, XVI^{e}.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A COMITIA was held on July 27th, Sir THOMAS BARLOW, Bart., K.C.V.O., being in the chair.

The following gentlemen having passed the required examinations were admitted Members of the College: Hildred Bertram Carlyll, M.D. Cantab., L.R.C.P., Ivor Jones Davies, M.B. Lond., Filippo Melandri, M.D. Bologna, John Parkinson, M.D. Lond., L.R.C.P., Edward Palmer Poulton, M.B. Oxon., Frederick George Thomson, M.D. Lond., L.R.C.P., and Arthur Gurney Yates, M.D. Edin.

Licences to practise physic were granted to 97 gentlemen who had passed the necessary examinations.

In conjunction with the Royal College of Surgeons of England Diplomas in Public Health were granted to the following candidates:—David Main Baillie, Samuel Lindsay Brohier, John Phillip Henry Davies, Reginald Inglis Douglas, William Henry Wilson Elliot, Lieutenant-Colonel, I.M.S., D.S.O., William Charles Dillon Hills, James Bonnell Howell, John Johnstone Jervis, Robert Henry Hatten Jolly, Thomas McCririck, John McKenzie, Captain, R.A.M.C., Bernard Moiser, Henry Pratt Newsholme, Jitendra Nath Rai, Bikrama Jit Sahni, Percy Herbert Stirk, William Reginald Margetts Turtle, Ernest Alfred Freear Wilkes, Charles Frederic Wood, and William Allan Young.

On the nomination of the President, the Council, and the Library Committee the following elections were made:—Censors: Dr. John Mitchell Bruce, Dr. David Bridge Lees, Dr. Samuel Hatch West, and Dr. Percy Kidd. Treasurer: Sir Dyce Duckworth, Bart. Emeritus registrar: Dr. Edward Liveing. Registrar: Dr. Joseph Arderne Ormerod. Harveian librarian: Dr. Norman Moore. Elected members of the library committee: Sir William Allchin, Dr. Humphry Davy Rolleston, Dr. Arthur Francis Voelcker, and Dr. Raymond H. P. Crawfurd. Curators of the museum: Sir William Henry Allchin, Dr. Seymour John Sharkey, Dr. Frederick William Andrewes, and Dr. William Hunter. Finance committee: Dr. Howard Henry Tooth, C.M.G., Dr. George Newton Pitt, and Dr. Hector William Gavin Mackenzie. Examiners: Chemistry—Mr. William Holdsworth Hurtley and Mr. Hugh C. H. Candy. Physics—Mr. Alfred Henry Fison and Mr. Herbert Stanley Allen. Practical pharmacy—Dr. Arthur Philip Beddard, Dr. Edmund Ivens Spriggs, Dr. William James Fenton, Dr. Alfred Ernest Russell, and Dr. Arthur Robertson Cushny. Physiology—Dr. Marcus Seymour Pembrey and Mr. Francis Gotch. Anatomy—Dr. Christopher Addison. Medical anatomy and principles and practice of medicine—Dr. Wilmot Parker Herringham, Dr. Richard Grainger Hebb, Dr. Lauriston Elgie Shaw, Dr. Judson Sykes Bury, Sir Hugh Reeve Beevor, Dr. James Galloway, Dr. Arthur Francis Voelcker, Dr. Wilfred James Hadley, Dr. Cyril Ogle, and Dr. Wilfred John Harris. Midwifery and diseases peculiar to women—Dr. Charles Montague Handfield-Jones, Dr. Arthur Hamilton Nicholson Lewers, Dr. Arthur Francis Stabb, Dr. George H. A. Comyns Berkeley, and Dr. John Shields Fairbairn. Public health: Dr. Henry Richard Kenwood (Part I.) and Dr. Louis C. Parkes (Part II.). Tropical medicine: Dr. Frederick William Andrewes (bacteriology) and Dr. William John Ritchie Simpson, C.M.G. (diseases and hygiene of the tropics). Murchison scholarship: Dr. Sidney Philip Phillips and Dr. Hector William Gavin Mackenzie.

The following communications were received from: 1. The clerk of the Privy Council, enclosing copies of the programme of the Third International Congress for the Study and Prevention of Infantile Mortality to be held at Berlin, Sept. 11th–15th next. 2. The Brighton and Sussex Medico-Chirurgical Society, concerning the extent of practice by unqualified persons, and the dangers arising therefrom. 3. The Imperial Merchant Service Guild, concerning tests for colour vision. 4. The registrar of the General Medical Council, enclosing a report from the Public Health Committee of the Council, concerning changes in the regulations for the Diploma in Public Health. (This matter was referred to the Committee of Management). 5. The secretary of the Royal College of Surgeons reporting proceedings of the Council of that College upon June 8th and July 13th last.

Dr. StClair Thomson was appointed a delegate of the College to the International Laryngo-Rhinological Congress to be held at Berlin, August 30th to Sept. 2nd of this year. On the nomination of the Council, Dr. S. J. Sharkey was appointed a representative of the College in the Senate of the University of London, Sir William H. Allchin having resigned.

Sir William S. Church, Bart., K.C.B., was, on the recommendation of the Executive Committee of the Imperial Cancer Research Fund, re-elected a member of that committee.

Dr. Arthur Newsholme was re-elected a member of the Executive Committee of the Imperial Cancer Research Fund.

The PRESIDENT announced that the Council had recommended that the Baly medal for distinction in the science of physiology should be awarded to Dr. William Dobinson Halliburton. He also announced that the Bissett Hawkins medal in hygiene had been awarded to Dr. Clement Dukes for his work on the Hygiene of Public Schools.

A report was received and adopted from the committee appointed to consider a paper, entitled "Suggestions to Medical Practitioners respecting Certificates of Causes of Death," submitted by the Registrar-General.

A report was received and adopted from the committee appointed to consider a letter from the Medico-Psychological Association of Great Britain and Ireland in which was suggested the institution of a Diploma in Psychological Medicine. The report was as follows:—

The committee appointed by the Comitia on March 2nd, 1910, to consider the request of the President of the Medico-Psychological Association that the College should institute a special Diploma in Psychological Medicine, reports as follows:—

That whilst it is inexpedient to establish a special diploma in one branch of medicine, it is desirable that medical practitioners practising in insanity should be encouraged to obtain a high standard of knowledge and efficiency in their profession.

The committee therefore recommends that Members of the College who desire to do so, should be permitted to present themselves for a further examination in Psychological Medicine, and, if they satisfy the examiners, have their success recorded on the letters testimonial of their Membership.

To this end the committee recommends the enactment of the following regulations:—

PROPOSED REGULATIONS.

1. Any Member of the College may ask permission to present himself for further examination in Psychological Medicine.

2. The further examination in Psychological Medicine shall be held on such dates as the Censors' Board may from time to time determine.

3. Candidates shall be examined in:—(1) Psychology, and the Study of Conduct in relation to Mental Disorder; and (2) Psychological Medicine, and the Jurisprudence of Insanity.

4. Candidates shall be examined by written questions on each of the subjects mentioned above; the practical knowledge of the candidates shall be tested in an Institution for the Insane, and the candidates shall be examined *vivâ voce* in all the subjects of the examination.

5. On the letters testimonial of every Member who satisfies the examiners in Psychological Medicine a statement to that effect shall be engrossed, and signed by the examiners, accompanied by a certificate by the registrar.

Form to be engrossed on the Letters Testimonial.

A.B. die mensis A.D.
in Medicinâ Psychologicâ examinatus satisfecit nobis Examinatoribus.
Ita testamur { A.B. / C.D. } Examinatores.

6. Every Member who satisfies the examiner will be permitted to add to any mention or description of his Membership words purporting that he obtained distinction in Psychological Medicine.

The annual report of the Imperial Cancer Research Fund was received.

The report dated June 27th from the Committee of Management was received and adopted. The report recommended:—

1. That the Darlington Technical College be added to the list of institutions recognised by the Examining Board in England for instruction in Chemistry and Physics.

2. That the Portsmouth Fever Hospital, Milton, be added to the list of fever hospitals recognised by the board for instruction in infectious diseases.

3. That Washington University, Washington, U.S.A., be placed on the list of universities whose graduates in medicine are admissible to the final examination of the board under the conditions of paragraph IV., Section III. of the Regulations.

4. That until further notice an additional examination in Part I. for the Diploma in Public Health be held in the month of April in each year.

Another report, dated July 11th, from the Committee of Management was received and adopted. The report recommended:—

1. That the following institution, which has been visited by a member of the committee and reported as fulfilling the requirements of the board, be added to the list of institutions recognised by the Examining Board in England for instruction in Chemistry, Biology, and Physiology: Newnham College.

2. That Dr. Norman Moore be appointed the Visitor to the examinations of the Egyptian Medical School for the examinations to be held in December next.

After some further formal business the PRESIDENT dissolved the Comitia.

THE RADIUM INSTITUTE.

THE Radium Institute, which was founded, at the suggestion of King Edward two years ago, by Sir Ernest Cassel and Viscount Iveagh, is to be formally opened on August 14th. This institution is devoted to the work of scientific research and to the skilled application of radium in the treatment of disease. On March 23rd the institute was inspected by His Majesty King George, who was accompanied by the Queen, and on July 10th it was again honoured with a visit by their Majesties Queen Alexandra and the Empress Marie Feódorovna of Russia. On the occasion of these visits demonstrations were given by the medical superintendent, Mr. A. E. Hayward Pinch, and by Mr. W. Lester Alton, director of the chemico-physical laboratories. Quite recently Madame Curie has isolated radium, and describes it as a white metal oxidising

FIG. 1.

The façade of the Radium Institute.

in water, burning paper, turning black on exposure to air, and having the property of adhering firmly to iron. It is, however, with the compounds of radium that treatment is carried out, and we find on inquiry that the Radium Institute in London has stored in its building a larger supply of radium than is possessed by any other institution in the world; and so priceless is the commodity from a commercial point of view that we hesitate to estimate in terms of pounds, shillings, and pence the value of the precious element at 16, Riding House-street.

The Radium Institute and the Medical Profession.

A letter dated May 6th, 1911, from Sir Frederick Treves, chairman of committee, addressed to the medical superintendent, so exactly indicates the line of professional conduct to be followed in work at the institute that we freely paraphrase it. The letter stated in the first place that it was desirable that the medical superintendent should limit as far as possible his responsibilities in connexion with the patients who attended at the institute to indication of the specific treatment to be employed in each case, as well as the details of that treatment; to ensuring that the treatment was carried out; and to declining to treat any unsuitable case. The diagnosis of the malady from which the patient is suffering will rest with the practitioner introducing the patient, and should the medical superintendent not agree with the diagnosis submitted he will discuss the matter with the practitioner; and should a third opinion be considered necessary, will call in, when the patient is a gratuitous one, a member of the honorary consulting staff. When difficulty as to diagnosis arises in the case of a paying patient, and a third opinion is needed, the practitioner will name the consultant unless he wishes to leave the nomination to the medical superintendent. But the patient must pay the fee of the consultant, no matter whether the consultation is held at the institute or at the consultant's house. In no case will the medical superintendent, acting on behalf of the institute, accept a fee for taking part in any consultation, and the honorary consulting staff, as a staff, are concerned only with the gratuitous patients treated at the institute, and no fee of any kind will be charged to such patients for any treatment carried out in the institute. For all special treatment requiring, for example, a gynæcologist, the paying patient must pay such fees as are usually paid for like services. The medical superintendent's responsibility for the care of patients does not, of course, extend outside the institute.

Sir Frederick Treves's full letter is so simple and clear a document that it might well be framed and hung in the corridors of the institute, if only to convince everyone that the institute cannot be made use of to put fees into the pockets of any specially selected members of the medical profession.

Regulations for Patients.

The following regulations for the admission of patients have been drawn up:—

Patients will only be treated at the Radium Institute in association with, and through the introduction of their medical adviser. At their first visit they must either be accompanied by their medical adviser or must bring with them his written statement of the case giving details of the treatment already employed. New patients will be seen on Tuesdays and Thursdays between the hours of 10 A.M. and 4 P.M., but the exact day and hour of any consultation must be arranged previously (by letter) with the medical superintendent, to whom all communications should be addressed.

Medical practitioners are cordially invited to be present during the treatment of their patients, and to assist in the same whenever practicable.

The medical superintendent on receiving a first inquiry from an individual for treatment posts off the following letter in reply:—

DEAR .....,—In reply to your letter of inquiry respecting the Radium Institute, I beg to inform you that patients can only be treated in association with, and through the introduction of their medical adviser. I shall, therefore, be pleased to forward full particulars to your medical man if you will favour me with his name and address.—Yours truly,

A. E. HAYWARD PINCH, Medical Superintendent.

On receiving an answer giving the name of the medical practitioner the medical superintendent writes to that gentleman in the following terms:—

DEAR .....,—In compliance with the request of your patient, M ..... I beg to forward you herewith particulars of the conditions under which patients are admitted to the Radium Institute for treatment, and the charges for the same.—Yours truly,

A. E. HAYWARD PINCH, Medical Superintendent.

The charges referred to are as follows:—

	£	s.	d.
For first consultation at the Radium Institute, the patient being accompanied by his or her medical adviser, or bringing from such medical adviser a written history of the case...	2	2	0
For treatment:			
1. When lesion is situated on external surface of body			
(*a*) With apparatus containing not more than 50 milligrammes of radium.			
Per sitting	2	2	0
(*b*) With apparatus containing more than 50 milligrammes of radium.			
Per sitting	4	4	0
2. When lesion is situated in cavity—e.g., larynx, uterus, urethra, &c.			
Per sitting	5	5	0

In regard to necessitous patients the following letter is sent to any such on application for free treatment:—

DEAR .....,—In reply to your letter of inquiry, I beg to inform you that necessitous patients are only admitted to free treatment at the Radium Institute if certified by their medical adviser to be suitable subjects for charity. If you will, therefore, be good enough to ask your medical man to fill up the enclosed certificate, and forward it to me, together with any notes with which he may furnish you, I will write fixing a day and hour for your attendance at the Radium Institute.—Yours faithfully,

A. E. HAYWARD PINCH, Medical Superintendent.

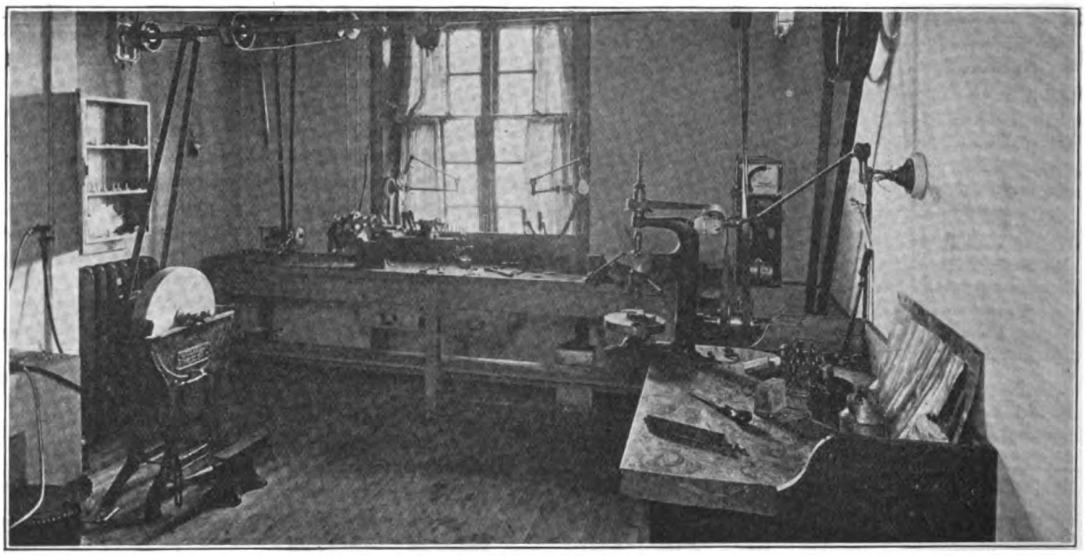
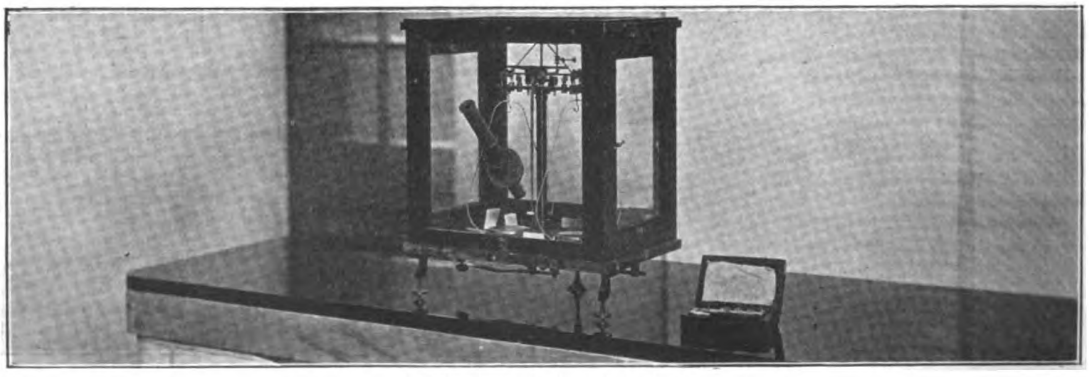
FIG. 6.



Engineer's shop, Radium Institute.

FIG. 7.



Alton's balance, Radium Institute.

The certificate referred to runs thus:—

I HEREBY CERTIFY THAT

M.....
residing at.....
is suffering from..... ; that ..... is in necessitous circumstances, and is to the best of my knowledge a fit and proper case for gratuitous treatment at the Radium Institute.

Name of Practitioner.....
Qualification.....
Address.....
Date.....

Medical practitioners are cordially invited to be present during the treatment of their patients, and to assist in the same whenever practicable.

Medical men desiring information concerning the activity of specimens of radium salts can have the necessary information supplied from the chemico-physical laboratory of the institute at the following scale of fees for the examination of radium salts and the examination or preparation of radium applicators.

	£	s.	d.
(*a*) Measuring the amount of radium contained in specimens of radium salts	2	2	0
(*b*) Measuring the amount of radium contained in various forms of radium applicators	2	2	0
(*c*) Analysis of the rays emitted from various forms of radium applicators	5	5	0
(*d*) Preparation of radium applicators. (To be made for medical men only.)			
1. Circular or square discs	2	2	0
2. Cylindrical and special designs	5	5	0
(*e*) Examinations of water, minerals, and the like, for radioactivity	2	2	0

Whilst reasonable care will be taken of all specimens and apparatus sent to the institute for examination, &c., it must be clearly understood that the examination of such specimens and apparatus is undertaken at the owner's risk, and that the institute cannot accept any liability with regard to the same.

Entering Riding House-street from Portland-place, the façade of the building of the institution presents itself as peculiarly suitable to the style of the architecture in its neighbourhood. Our illustration (Fig. 1) affords an excellent representation of the building.

On entering the institute we find on the ground floor the necessary accommodation provided for the reception of patients both well-to-do as well as necessitous, and for the diagnosis of the cases presented. The first floor is fitted up for the treatment of patients, the second floor is devoted to scientific research, and the third floor is reserved for the workshops and the tools required to make the institution quite independent of all outside help in the matter of apparatus of all kinds, scientific and otherwise.

The consulting-rooms, one of which is shown in Fig. 2, are five in number on the ground floor, two of them being for well-to-do patients, two for the poor, and one for gynæcological examination. The equipment throughout the building is of the most aseptic character, and this characteristic of the place is well seen in the out-patient waiting-room, where the walls are tiled, the corners rounded, and the floor made of teak.

A further indication of the modern equipment of the institution is noticed in the fact that one of Tilley's chairs specially constructed for Killian's intubation method is already installed.

The first floor of the building is given up to treatment of patients, there being cubicles for treatment for the poor and for the rich. Fig. 3 indicates better than a description in words the style of one of these cubicles.

On the second floor ample accommodation is supplied for scientific research. Fig. 4 shows the pathological laboratory, and anyone acquainted with modern research would notice at once the latest pattern Zeiss microscope fitted with the most reliable appliances for dark-ground illumination; an up-to-date Minot microtome will not escape observation, nor a Leitz microtome freezing apparatus. On the same floor Mr. Alton, the director of the chemico-physical work, has his laboratory, and Fig. 5 indicates very clearly the excellent arrangements provided for this important branch of scientific study. The photographic room deserves a word of praise, and indeed it must have been fitted up absolutely regardless of expense.

On the third floor is a neat and well-equipped engineer's shop (Fig. 6), in which all the apparatus required for the work of the institution is manufactured.

The basement contains a room specially fitted for Mr. Alton's balance. This balance (Fig. 7) rests on a slab supported by two pillars, and these pillars pass through the foundations to such a depth that absence of any vibration is assured. Close to this room is the commodious safe for the storing of the radium.

The Radium Institute has for its patron His Majesty the King, and its presidents are the Viscount Iveagh and Sir Ernest Cassel. The Executive Committee is composed of Sir Frederick Treves, the Hon. W. E. Guinness, Mr. Felix Cassel, the Hon. J. Strutt, Sir Lauder Brunton, Sir William Ramsay, Sir Malcolm Morris, and Sir Joseph John Thomson. The honorary consulting staff consists of Mr. W. H. Clayton-Greene, Dr. Herbert French, Mr. W. H. H. Jessop, Dr. J. H. Sequeira, Dr. W. H. H. Tate, Mr. Herbert Tilley, and Mr. J. W. Thomson Walker. The technical assistant is Mr. John F. Holding, and the architect is Mr. T. P. Figgis, F.R.I.B.A.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

THE annual meeting of this association was held on July 13th and 14th at the Royal College of Physicians, Dublin, under the presidency of Dr. JOHN MACPHERSON.

Regret was expressed at the resignation of the veteran editors of the Journal of the association, Dr. H. Rayner and Dr. A. R. Urquhart, and Mr. H F. HAYES NEWINGTON (the treasurer) expressed the high appreciation by the association of their prolonged and able services.

Mr. HAYES NEWINGTON moved the adoption of the report of the Committee on the Medical Inspection of School Children and paid a high tribute to the good work done at Darenth.

The installation of the new President, Dr. William R. Dawson, followed a vote of thanks to the out-going President, Dr. Macpherson. Dr. DAWSON presented, on behalf of the subscribers, a silver casket and an illuminated address to Dr. Edward Courtenay, on his retirement from the office of Inspector of Lunatic Asylums in Ireland.

Dr. DAWSON, in his presidential address, discussed the geographical distribution of insanity in Ireland and compared it with that of other conditions, such as density of population, pauperism, and poverty, emigration, the death-rate (both general and tuberculous), criminality, and alcoholism, and illustrated his remarks with statistical diagrams. These showed that insanity prevailed in the agricultural counties, chiefly of the south and east, Ulster and Connaught being relatively free, and that pauperism had a similar distribution. It bore some, but not a marked, relation in local incidence to that of the emigration rate, criminality, and chronic alcoholism, but none, apparently, to density of population, rateable value of land, proportion of aged persons, death-rate, or drunkenness. The amount of insanity ascribed to alcohol in Ireland was small. Secondarily, it was found that pauperism and poverty were not necessarily alike in distribution. The President was hopeful for the future.

Dr. WILLIAM GRAHAM (Belfast) read a paper on Psychotherapy in Mental Disorder, a subject which, though little discussed here, had attracted widespread attention in France, Germany, and America, where men of international reputation had applied the methods with, it was said, singular success. The classical methods of psychotherapy were: (*a*) suggestion, waking and hypnotic; (*b*) therapeutic conversation; (*c*) psycho-analysis; (*d*) occupation; and (*e*) re-education. (*a*) Suggestion as a therapeutic agent had been over-estimated; nevertheless, it was of value in certain types—e.g., alcoholism, sexual perversion, obsessions, phobias, multiple personality, and other forms of mental disturbance. (*b*) Therapeutic conversation (Dubois's method) consisted in explaining to the patient the origin and significance of his disorder so that the explanation became persuasion. This method was valuable in the less intractable types of disorder before the perverted idea had become too deeply rooted. But the patient was liable to get too dependent on the therapeutist, so that when removed from his influence a relapse was likely; and it was applicable only to a group of milder cases. (*c*) Psycho-analysis. This method (identified with the name of Freud) rested on the view that many disorders arose from the inability of the personality to assimilate certain experiences, such as those of a painful emotional character, and from the conflict thus set up between opposing groups of thought. The therapeutics consisted in making

clear to the patient the source of this conflict by bringing into the clear light of consciousness the submerged factor, and in thus re-establishing mental unity and integrity. This method had given best results in long-standing obsessions, psychasthenias, phobias, hysteria, and paranoid states. Freud's view over-emphasised the element of sexuality. The method was applicable to some types, but the tendency to confine psychotherapy to it must be rejected. (*d*) Occupation meant all methods that distracted the patient's attention from himself. Its main value lay in its power to train the attention. (*e*) Re-education, in Dr. Graham's opinion, was the crown of the whole psychotherapeutic movement. In some cases it implied suggestion and therapeutic conversation, in others psycho-analysis, in still others occupation; in all it sought to restore the normal psychic balance by teaching the patient how to regulate emotion, train the power of will, and direct properly his attention. In the primary stages of all mental developments, in the formation of character, in the beginning of pathological states, the value of this method could not be over-estimated.—The paper was discussed by Dr. MARY MACKENZIE, Dr. C. H. BOND, Mr. J. O'CONOR DONELAN, Dr. E. MAPOTHER, Dr. HELEN BOYLE, Dr. T. W. MCDOWALL, Dr. J. G. SOUTAR, and Mr. M. J. NOLAN.—Dr. GRAHAM replied.

Dr. M. A. COLLINS (Ewell Colony) read a paper entitled "Causes of Sudden Death in Epilepsy and some Points in the Treatment of Epilepsy." Dr. Marchand had said that, apart from accident, an epileptic fit never caused death; yet that authority had collected 15 cases of sudden death during a fit—two of them in his own experience. The epileptic colony at Epsom had been open seven years, and there 30,000 fits were recorded during the past year. Probably 200,000 fits had occurred since the establishment was opened; and 10 cases were recorded in which death occurred during, or almost immediately after, a fit. In 2 there was choking after food, and 1 death ensued from suffocation during a fit at night time. Of the 7 cases remaining, in 1 there was mitral and aortic disease together; in 2 there was adherent pericardium; in 3 advanced fatty disease of the heart, with evidence of chronic heart failure; and in the other cerebral tumour was found. He regarded the colony treatment as ideal, and it resulted in a great physical improvement of the patients. There would shortly be opened at Ewell a new hospital villa of the most recent type, to accommodate 50 acute patients. His results from changes in dietary had been somewhat contradictory, but he found fewer fits per night after a meat dinner than after fish. The results favoured a diminution of meat, but not its absence. The effect of bromides had been very variable. In two cases which were intolerant of bromide opium was proving useful. Digitalis in one who had a large number of fits brought about an 80 per cent. reduction in the fits.—The PRESIDENT said that when investigating the condition of the city of Dublin for the Royal Commission on the Feeble-minded he found that epilepsy was regarded as more of a family disgrace than was insanity. It was considered that knowledge of a fit on the part of the employer would lose the man his work. Expense was an important matter for a poor country like Ireland.—Dr. J. B. SPENCE, Dr. D. BOWER, Mr. HAYES NEWINGTON, Dr. J. F. DIXON, Mr. B. C. A. LEEPER, Dr. T. DRAPES, Mr. NOLAN, Dr. BOND, Dr. FLETCHER BEACH, Dr. G. W. GREENE, Mr. E. D. O'NEILL, and Mr. DONELAN discussed the paper, and Dr. COLLINS replied.

In the evening a banquet was held at the Royal College of Surgeons under the presidency of Dr. Dawson. There was a large company present, including his Excellency the Lord Lieutenant of Ireland, the Under Secretary for Ireland, the Presidents of the Colleges of Physicians and Surgeons, the Recorder of Dublin, the Bishops of Canea, Meath, and Clogher, as well as Dr. Macpherson, Mr. Hayes Newington, the Chairman of the Prisons Board, Mr. T. I. Considine (Inspector of Lunatic Asylums in Ireland), Dr. Drapes, and Dr. Percy Smith. The Lord Lieutenant, in reply to the toast of his health, proposed by Dr. MACPHERSON, referred in enthusiastic terms to the recent Royal visit to the city, and expressed his deep sympathy with the work carried on by those who laboured at the treatment of the insane. "The Medico-Psychological Association" was proposed by the Vice-Chancellor of the National University of Ireland in a speech in which he advocated the creation of a B Sc. degree for a knowledge of mental diseases. Dr. DAWSON, in replying, spoke of the monotony of the work, and said that workers in the field needed all the encouragement they could get. "The Visitors" was proposed by Dr. DRAPES, and acknowledged by the Bishop of Canea and the President of the College of Surgeons. The Lord Lieutenant proposed a hearty vote of thanks to the President.

Other papers, read on the following day, were as follows: The Personal Equation in Alienism, by Dr. DRAPES (Enniscorthy); Note on Hereditary Insanity from a Practical Standpoint, by Mr. LEEPER; Certain Observations on the Morbid Histology of General Paralysis, by Professor SHAW BOLTON; Clinical Evidence *re* the Toxic Nature of Insanity, by Dr. COLIN F. F. MCDOWALL (Cheddleton) and Dr. W. T. SEWELL (Newcastle), was read by Dr. MCDOWALL; Mental Symptoms in Association with Choreiform Disorders, by Dr. MAPOTHER.

In the afternoon, by the kindness of the Fellows of the Royal Zoological Society, a garden party was held at the Society's gardens.

NATIONAL VETERINARY CONGRESS.

THE twenty-ninth annual meeting of the National Veterinary Association was held at Carnarvon on July 26th and 27th. Even if the attendance at the Congress was not large, all those present were extremely keen, and much useful information was presented and exchanged. Mr. T. SALUSBURY-PRICE presided, and in his address referred to the recent finding of the Tuberculosis Commission.

A paper on Veterinary Education in Relation to Public Health was read by Dr. O. CHARNOCK BRADLEY, who remarked that the recent rapid advance of veterinary science within the past 20 years is shown by the establishment of specialism within the ranks of the profession. Previously the training of the student, said Dr. Bradley, resolved itself into producing a general practitioner. Now the potential specialist has to be taken into account in the planning of the curriculum. All students upon obtaining a diploma will not become general practitioners; a proportion of them will enter the public services and will almost inevitably sooner or later have to concern themselves with questions of public health. Therefore the teaching of to-day differs markedly from that of 20 years ago. It would certainly not be sufficient to say that the duty of the veterinary officer of health ceases when he has succeeded in procuring a safe and efficient meat- and milk-supply, though this apparently in the minds of many sums up his function. In the matter of milk-supply a knowledge of the conditions under which the milk producer should be placed is necessary. This involves the consideration of suitable housing, feeding, water-supply, ventilation, and drainage. In other words, the officer must be conversant with the principles of building construction, the different nutritive values of foodstuffs and their effect upon the quantity and quality of milk yield, the possible adulterants and impurities of food and their effects, the source, storage, adequate amount, and distribution of water-supply, as well as the injurious effects of impurities of water, the necessary amount of air space and the methods by which excreta may be removed and disposed of, and the means in general by which the milk-yielding animals may be maintained in a state of health conducive to the production of sound milk. In his work relating to meat inspection the veterinary officer must use his knowledge of anatomy, of the peculiarities incident to breed, sex and age of the effects of foodstuffs, of the pathological changes met with in the organs and flesh of the domestic animals, and the possibility of their producing detriment to the health of the consumer. Without clinical veterinary knowledge the would-be supervisor of the milk- and meat-supply is at a great disadvantage. The medical officer of health and the veterinary officer work along the same lines up to a certain point, but the paths of the two soon diverge. The medical officer has to concern himself with the housing and feeding of man and the combating of diseases, many of which are peculiar to the human race. The veterinary officer has to regard similar features as they apply to animals. In particular he must be conversant with the clinical and pathological features of those diseases of animals which are transmissible to man.

Mr. J. W. BRITTLEBANK (Manchester), in discussing the

paper, said that it should not be assumed that the education of the veterinary student is inefficient, but a special training in the subjects laid down by Dr. Bradley would produce an ideal veterinary officer of health.

Mr. W. WOODS (Wigan) urged the profession to prepare men to fill the new appointments that are likely to be made. In order to carry out sound supervision of milk-supply it will be necessary to obtain a mixed sample of milk from the dairy, and if tubercle bacilli are present then it will be necessary for every cow to be tested. Large laboratories will have to be established all over the country, and medical and veterinary practitioners will be responsible for the efficient working of these establishments.

The following motion was proposed by Professor WOODRUFFE and carried :—

That the National Veterinary Association, in general meeting assembled, approves the action of the Council of the Royal College of Veterinary Surgeons in appointing a committee to consider the question of education in public health matters, and desires to urge upon the Council the need for prompt action in the interests of public health.

A paper on Sclerostomiasis in Equines, presented by Dr. H. E. ANNETT, provided an interesting subject for debate. Dr. Annett observed that amongst the horses and donkeys which were under his charge for treatment for the production of various therapeutic sera the ravages of this disease forcibly attracted his attention. The nearest allies of the sclerostomes are the parasites of the genus ankylostomum or uncinaria, and the study of the members of this genus in man more particularly, but also in the dog and other animals, has, as is now well known, given most remarkable and surprising results, but these are greatly surpassed by those which have arisen in the course of the more recent work on the sclerostomes. Dr. Annett carried out a series of experiments with the object of discovering if drugs could be conveyed to the seat of infection in a sufficient state of concentration to be effective. For this purpose he employed gelatine capsules coated with cellulose, but the experiments have not yet reached a stage at which any definite knowledge in this particular direction can be arrived at.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns 7921 births and 4210 deaths were registered during the week ending July 29th. The revised estimate of the population of these towns in the middle of this year is 16,157,797 persons. The annual rate of mortality in these towns, calculated on this revised estimate, which had been equal to 12·0, 11·8, and 12·1 per 1000 in the three preceding weeks, further rose to 13·6 in the week under notice. During the first four weeks of the current quarter the annual death-rate in these towns averaged 12·4 per 1000, while in London during the same period the mean annual death-rate did not exceed 11·9 per 1000. The recorded annual death-rates in the 77 towns during last week ranged from 6·5 in West Hartlepool, 6·8 in Hornsey, 6·9 in Reading, and 7·0 in Stockton-on-Tees to 19·1 in Wolverhampton, 19·2 in Liverpool, 19·5 in Stoke-on-Trent, and 20·8 in Bootle. The 4210 deaths from all causes in the 77 towns last week exceeded by 459 the low number recorded in the previous week, and included 722 which were referred to the principal epidemic diseases, against numbers increasing from 268 to 423 in the four preceding weeks. Of these 722 deaths 533 resulted from infantile diarrhœa, 62 from measles, 56 from whooping-cough, 42 from diphtheria, 18 from scarlet fever, and 11 from enteric fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases was equal to 2·3 per 1000, against 1·0 and 1·4 in the two preceding weeks. The deaths of infants under two years of age attributed to diarrhœal diseases in the 77 towns, which had increased from 70 to 236 in the four preceding weeks, further rose last week to 533, and caused the highest annual rates of 3·7 in Birmingham, in Bootle, and in Cardiff, 3·9 in Dewsbury, 4·4 in Birkenhead, 4·8 in St. Helens, and 5·8 in Wigan. The 62 fatal cases of measles were equal to the number recorded in the previous weeks, and included 21 in London and its suburban districts, 5 in Wolverhampton and in Liverpool, 4 in Bristol, 3 in Bolton, and 3 in Manchester. The deaths referred to whooping-cough, which had been 43 and 52 in the two preceding weeks, rose again last week to 56; 14 deaths were recorded in London and its suburban districts, 5 in Manchester and in Sunderland, and 4 in Hull and in Cardiff. The fatal cases of diphtheria, which had been 45 and 40 in the two preceding weeks, were 42 last week, of which 12 were registered in London and its suburban districts, 4 in Liverpool and in Blackburn, and 3 in Stoke-on-Trent and in Birmingham. The 18 deaths from scarlet fever were 4 fewer than the number in the preceding week, and included 4 in Liverpool, 2 in London, and 2 in Bradford. The 11 fatal cases of enteric fever were equal to the number returned in the previous week, and included 2 in Wigan. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had steadily increased from 982 to 1358 in the 15 preceding weeks, had further increased to 1412 on Saturday last; 209 new cases of this disease were admitted to the hospitals during the week, against 191, 204, and 199 in the three previous weeks. These hospitals also contained at the end of last week 842 cases of diphtheria, 316 of measles, 27[illegible] of whooping-cough, and 48 of enteric fever, but not one of small-pox. The 1185 deaths from all causes in London last week showed an increase of 200 upon the low number returned in the previous week, and included 115 which were referred to diseases of the respiratory system, against 119 and 113 in the two previous weeks. The deaths attributed to different forms of violence in the 77 towns, which had been 194 and 188 in the two preceding weeks, declined to 173 last week, and 347 inquest cases were registered. The causes of 28, or 0·7 per cent., of the deaths registered in the 77 towns during the week under notice were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death during last week were duly certified in London and its eight suburban districts, in Bristol, Bradford, Newcastle-on-Tyne, Nottingham, Stoke-on-Trent, Salford, and in 46 other smaller towns; the 28 uncertified causes of death in the 77 towns last week included 6 in Birmingham, 4 in Liverpool, 3 in South Shields, 2 in Handsworth (Staffs.), and 2 in Sheffield.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns, having an estimated population of 1,710,291 persons in the middle of this year, 835 births and 488 deaths were registered during the week ending July 29th. The annual rate of mortality in these towns, which had been 14·9 and 13·9 per 1000 in the two preceding weeks, rose again last week to 14·9. During the first four weeks of the current quarter the annual death-rate in these Scotch towns averaged 14·6, and was 2·2 per 1000 above the mean rate during the same period in the large English towns. The annual death-rate during last week in the eight Scotch towns ranged from 9·9 and 11·7 in Aberdeen and Paisley to 16·2 in Leith and 22·2 in Greenock. The deaths from all causes in the eight towns last week showed an increase of 31 on the number in the previous week, and included 73 which were referred to the principal epidemic diseases, against 57 and 63 in the two previous weeks; of these deaths, 40 resulted from diarrhœa, 17 from whooping-cough, 6 from diphtheria, 4 from measles, 4 from scarlet fever, 1 from enteric fever, and 1 from small-pox. The mean annual death-rate from these epidemic diseases in the eight towns last week was equal to 2·2 per 1000, the mean rate last week from the same diseases in the 77 English towns having been 2·3. The deaths from diarrhœa, which had increased from 14 to 28 in the three preceding weeks, further rose last week to 40, and included 33 of infants under two years of age; 23 deaths occurred in Glasgow, 7 in Edinburgh, 4 in Greenock, and 3 in Leith. The fatal cases of whooping-cough, which had been 23 and 17 in the two previous weeks, were again 17 last week, of which 12 were recorded in Glasgow. The 6 deaths attributed to diphtheria were 3 in excess of the number in the previous week, and included 2 in Glasgow and 2 in Perth. The 4 fatal cases of measles showed a decline from the numbers in recent weeks and included 3 in Glasgow. The 4 deaths from scarlet fever were equal to the number returned in the

preceding week. The fatal case of enteric fever was registered in Glasgow, and that of small-pox in Dundee. The deaths referred to diseases of the respiratory system in the eight towns, which had been 47 and 51 in the two preceding weeks, were 48 in the week under notice, and were 13 below the number in the corresponding week of last year. Of the 488 deaths from all causes in the eight towns last week, 159, or 33 per cent., were recorded in public institutions, and 18 were attributed to different forms of violence. The causes of 18, or 3·7 per cent., of the deaths in the eight towns last week were not specified or not certified; in the 77 English towns the proportion of uncertified causes of death during the week did not exceed 0·7 per cent.

HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,149,495 persons in the middle of this year, 654 births and 362 deaths were registered during the week ending July 29th. The annual rate of mortality in these towns, which had been equal to 16·7 and 16·8 per 1000 in the two preceding weeks, declined to 16·4 in the week under notice. During the first four weeks of the current quarter the annual death-rate in these Irish towns averaged 16·0 per 1000; in the 77 English towns the mean annual death-rate during the same period did not exceed 12·4, while in the eight Scotch towns it equalled 14·6 per 1000. The annual death-rate during the week under notice in the 22 Irish towns was equal to 22·5 in Dublin (against 13·7 in London), 14·2 in Belfast, 16·3 in Cork, 11·5 in Londonderry, 13·6 in Limerick, and 15·2 in Waterford; in the 16 smallest of these Irish towns the mean annual death-rate last week did not exceed 9·5 per 1000. The 362 deaths from all causes in the 22 towns last week showed a decrease of 9 from the number in the preceding week, and included 87 which were referred to the principal epidemic diseases, against 35 and 53 in the two preceding weeks; these 87 deaths were equal to an annual rate of 3·9 per 1000, which was 1·5 above the mean rate from the same diseases in the 77 English towns. These 87 deaths in the Irish towns last week from the principal epidemic diseases included 70 from diarrhœal diseases, 7 from measles, 6 from whooping-cough, 2 from scarlet fever, 1 from enteric fever, and 1 from diphtheria, but not one from small-pox. The deaths attributed to diarrhœal diseases, which had increased from 8 to 36 in the three preceding weeks, further rose last week to 70, and included 62 of infants under two years of age; of these 70 deaths, 39 occurred in Dublin and 24 in Belfast. The 7 deaths from measles were 3 in excess of the number in the previous week and were all registered in Dublin. The 6 fatal cases of whooping-cough were equal to the number returned in the previous week, and included 3 in Dublin. The 2 deaths from scarlet fever and the fatal cases of enteric fever and diphtheria were all recorded in Dublin. The deaths referred to diseases of the respiratory system in the 22 towns, which had been 52 and 40 in the two preceding weeks, were 44 in the week under notice. Of the 362 deaths from all causes in the 22 towns last week, 108, or 30 per cent., were recorded in public institutions, and 6 were referred to different forms of violence. The causes of 8, or 2·2 per cent., of the deaths registered in the 22 towns last week were not certified either by a registered medical practitioner or by a coroner after inquest; the proportion of uncertified causes of death during the week under notice did not exceed 0·7 per cent. in the 77 large English towns, and was equal to 3·7 per cent. in the eight principal Scotch towns.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Staff Surgeon: F. E. Bolton to the *Hindustan*. Surgeon: A. V. J. Richardson to Chatham Hospital.

ROYAL ARMY MEDICAL CORPS.

The undermentioned Lieutenant-Colonels retire on retired pay: Sir Joseph Fayrer, Bart., Thomas H. F. Clarkson, David M. Saunders, and Herbert W. Austin (dated July 29th, 1911); and George W. Brazier-Creagh, C.M.G., and Daniel Hennessy (dated August 2nd, 1911).

The undermentioned Majors to be Lieutenant-Colonels: Bertal H. Scott, vice J. R. Forrest, retired (dated June 21st, 1911); Brevet Lieutenant-Colonel Oliver A. Julian, C.M.G., vice B. H. Scott, supernumerary to establishment (dated June 21st, 1911); and Eustace A. Burnside, vice H. L. E. White, retired (dated July 3rd, 1911).

The undermentioned Majors are placed on retired pay (dated July 28th, 1911): Robert J. D. Hall, Charles E. G. Stalkartt, Christopher J. Healy, and Thomas J. Lenehan.

Major Francis J. Wade-Brown retires on retired pay (dated July 29th, 1911).

The undermentioned Lieutenants are confirmed in their rank: Charles M. Finny, James D. Kidd, William S. R. Steven, Gordon Wilson, Edward G. S. Cane, Francis A. Robinson, William A. Frost, Douglas Reynolds, Charles D. K. Seaver, William T. Graham, Walter Bisset, William L. E. Fretz, and Patrick Hayes.

Lieutenant-Colonel T. Daly, commanding the Station Hospital at Dalhousie, has been appointed for duty at the Station Hospital, Peshawar Cantonment. Lieutentant-Colonel H. H. Brown has been transferred from Rawal Pindi to take up charge of the Military Hospital at Murree. Lieutenant-Colonel C. C. Reilly, at present holding medical charge of the Royal Military College at Sandhurst, has been selected for a tour of service with the Southern Army in India. Lieutenant-Colonel S. B. Wilson has been placed under orders by the War Office to proceed for a tour of duty at Jamaica during the coming trooping season. Major W. A. S. J. Graham has been transferred from Nowgong to the Station Hospital at Neemuch for duty. Major O. L. Robinson, from Meerut Cantonment, has joined at Kirkee. Major P. J. Probyn, D.S.O., on completion of a tour of service in North China, has been appointed to the Irish Command. Major K. B. Barnett, from Shorncliffe, has taken up duty at Eastbourne as medical officer in charge of effective troops. Major J. C. Jameson, on return from duty at Cairo, has been posted to Woolwich District. Major S. H. Withers, from Ambala Cantonment, has been appointed Senior Medical Officer at Gharial Camp, Murree Hills. Major G. S. Crawford, from Wormwood Scrubs Cavalry Camp, has returned to duty in the Irish Command. Major F. R. Buswell, from Kamptee, has been appointed to the Station Hospital at Jubbulpore. Major W. B. Wingfield, from Agra, has been appointed for duty at Chakrata. Captain M. F. Foulds, specialist in advanced operative surgery at Belfast, has been placed under orders to proceed to Mauritius during the coming trooping season. Captain E. S. Worthington, M.V.O, has been selected by the War Office for a tour of duty in North China. Captain W. F. Tyndale, from Kilbride Camp, has joined for duty at Dublin. Captain G. H. J. Brown, on completion of a tour of service in India, has been appointed to the Military Hospital at Strensall. Captain E. J. H. Luxmoore has been transferred from Canterbury to Dover.

INDIAN MEDICAL SERVICE.

Lieutenant-Colonel A. L. Duke, first-class agency surgeon and administrative medical officer of the North-West Frontier Province, has been appointed to officiate as Residency Surgeon and Chief Medical Officer of Baluchistan during the absence on leave pending retirement of Lieutenant-Colonel W. A. Sykes, D.S.O. H.E. the Governor of Bombay in Council has appointed Lieutenant-Colonel A. Street on return to duty to act as Senior Surgeon and Professor of Surgery to the Grant Medical College, Bombay, in succession to Major V. B. Bennett. Major A. T. Gage, director of the Botanical Survey of India, has been granted three months' leave of absence. Captain S. C. Chuckerbutty has been appointed Special Plague Medical Officer in the Irrawaddy Division. Captain D. G. Rai has been granted combined leave of absence from India for 15 months. Captain R. D. Saigol has been placed on special deputation duty at Amritsar. The services of Captain C. C. Murison have been placed at the disposal of the Home Department for duty at Surat as Civil Surgeon.

TERRITORIAL FORCE.

Royal Army Medical Corps.

2nd Home Counties Field Ambulance, Royal Army Medical Corps: Major David L. Hamilton to be Lieutenant-Colonel (dated June 17th, 1911).

2nd London (City of London) Field Ambulance, Royal Army Medical Corps: Major William Salisbury Sharpe, from the 3rd London (City of London) Field Ambulance, Royal Army Medical Corps, to be Major (dated July 1st, 1911).

2nd North Midland Field Ambulance, Royal Army Medical Corps: Lieutenant Evan L. Jenkins resigns his commission (dated July 29th, 1911).

For attachment to Units other than Medical Units.—William Howard Edwin Stewart to be Lieutenant (dated April 14th, 1911).

INDIAN MEDICAL SERVICE EXAMINATIONS.

The following are the names of the successful candidates, arranged in order of merit, at the examination for Commissions in His Majesty's Indian Medical Service, which was held at the Royal Army Medical College and at the Examination Hall, Victoria Embankment, on July 24th, 25th, 26th, 27th, 28th, and 29th:—

	Marks.
John Alexander Sinton, M.B., B.Ch., B.A.O. R.U.I., D.P.H. Cantab., D.T.M. Liverp., Queen's College, Belfast	3806
Denis Fitzgerald Murphy, M.B., B.Ch., B.A.O. R.U.I., University College, Cork	3721
Edward Randolph Armstrong, M.B., Ch.B. Liverp., D.P.H. Cantab., D.T.M. Liverp., Liverpool University	3572
Charles James Stocker, M.B., B.C., B A. Cantab., M.R.C.S., L.R.C.P., Cambridge University and St. Bartholomew's Hospital	3414
Eric Edward Doyle, L.R.C.P. & S. Edin., L.F.P.S. Glasg., Royal Colleges, Edinburgh	3346
Cyril Macdonald Plumptre, M.R.C.S., L.R.C.P., Guy's Hospital	3303
Archibald Wallace Duncan, M.R.C.S., L.R.C.P., St. Mary's Hospital	3299
Edward Austen Penny, M.B., B.S. Lond., M.R.C.S., L.R.C.P., Guy's Hospital	3257
George Blenkhorn Harland, M.B., B.S. Lond., Guy's Hospital and Durham University	3243
Leon Francis Brandenbourg, M.B., C.M. Madras, M.R.C.S., L.R.C.P., Madras Medical College and King's College Hospital	3238
John Edward Scudamore, M.B., B.S. Lond., London Hospital	3233
Henry Lewis Barker, M.B., B.S. Lond., M.R.C.S., L.R.C.P., St. Mary's Hospital	3186

ROYAL ARMY MEDICAL CORPS EXAMINATION.

The following is the list of successful candidates for commissions in the Royal Army Medical Corps, for which 44 candidates entered:—

	Marks.
B. H. H. Spence, M.B., Ch.B. Edin., Edinburgh University	622·5
W. B. Laird, M.R.C.S. Eng., L.R.C.P. Lond., St. Thomas's Hospital	606
D. W. Bruce, M.B., Ch.B. Univ. Aberd., Aberdeen University	568
H. S. Blackmore, M.R.C.S. Eng., L.R.C.P. Lond., L.D.S. R.C.S. Eng., University College Hospital	567
E. S. Calthrop, M.B., B.S. Lond., M.R.C.S. Eng., L.R.C.P. Lond., Charing Cross Hospital	565
L. Buckley, M.B., B.Ch. Liverp., M.R.C.S. Eng., L.R.C.P. Lond., Liverpool University	564
F. R. B. Skrimshire, M.R.C.S. Eng., L.R.C.P. Lond., St. Thomas's Hospital	555·5
R. T. Vivian, M.R.C.S. Eng., L.R.C.P. Lond., St. Bartholomew's Hospital	553
T. B. Osmond, M.R.C.S. Eng., L.R.C.P. Lond., B.A. Cantab., University of Cambridge and St. Bartholomew's Hospital	550
E. C. Deane, L.R.C.P. & S. Irel., L.M., Royal Colleges of Physicians and Surgeons, Ireland	549
S. P. Sykes, M.B., Ch.B. Liverp., Liverpool University	544
R. Davidson, M.B., Ch.B. St. And., Dundee University	542
E. G. H. Cowen, M.B., B.S. Lond., M.R.C.S. Eng., L.R.C.P. Lond., Charing Cross Hospital	541
E. B. Allnutt, M.R.C.S. Eng., L.R.C.P. Lond., St. Bartholomew's Hospital	537
J. M. Elliott, M.B., B.Ch., B.A., B.A.O. Dub., L.M., Trinity College, Dublin	535
H. E. Todd, M.B., Ch.B. Edin., Edinburgh University	529
J. L. Ritchie, M.B., Ch.B. Birm., M.R.C.S. Eng., L.R.C.P. Lond., Birmingham University	524·5
M. Drummond, L.R.C.P. & S. Irel., L.M., University College, Dublin, and St. Bartholomew's Hospital	522
A. G. J. MacIlwaine, L.R.C.P. & S. Irel., Queen's University, Belfast	520
W. Stewart, M.B., Ch.B. Edin., Edinburgh University	516

ITALIAN DECORATIONS FOR MEMBERS OF THE SERVICES.

The King has given the undermentioned officers His Majesty's Royal licence and authority to accept and wear decorations which have been conferred upon them by His Majesty the King of Italy in recognition of services rendered by them at the time of the earthquake in Southern Italy in the year 1908:—

Commander of the Order of St. Maurice and St. Lazarus: Surgeon-General James Gaussen MacNeece, Principal Medical Officer, 8th (Lucknow) Division, India.

Commander of the Order of the Crown of Italy: Major Gilbert Stewart Crawford, Royal Army Medical Corps.

Officer of the Order of the Crown of Italy: Captain Henry Stewart Anderson, Royal Army Medical Corps; Captain Harold Charles Winckworth, Royal Army Medical Corps; Captain Percy Arnold Lloyd-Jones, Royal Army Medical Corps; and Surgeon-Captain Robert Randon, Royal Malta Artillery.

Correspondence.

"Audi alteram partem."

INFLAMMATION AND MALIGNANT DISEASE.

To the Editor of THE LANCET.

SIR,—My excuse for sending this communication must be that in the researches which have been made on the origin of cancer, and which I have not the slightest desire to minimise, enough attention perhaps has not been paid to the relation between epithelioma and scirrhus and chronic inflammation. Long ago it was shown how frequently chronic mastitis preceded cancer of the breast. Still, I believe it was looked upon as a more or less accidental occurrence and not a *necessarily* pre-existing condition. Now what does chronic inflammation mean? It means that the inflamed tissue is invaded by a multitude of leucocytes, and continues to be invaded for an indefinite length of time. But at the end of this period a change seems to take place according to the age and resisting power not of the patient but of the tissue. In vigorous tissue these leucocytes are either absorbed or thrust forth in the form of an abscess. Where this does not happen and senility of tissue has taken place, resisting power having vanished, a malignant growth forms. This conclusion may be applied to the parts of the body where external cancers most frequently occur. In the tongue, as far as my experience goes, I have always been able to trace the malignant growth to a pre-existing source of irritation, as a sharp tooth or tooth-plate; in the lip to the well-known short clay pipe, or even to a projecting tooth; in the rectal cancers to fistula or fissures. And there is no doubt examples of pre-existing chronic inflammation may be quoted to almost any extent. So that I think one is justified in saying that chronic inflammation produced by some irritation or other is an invariable precedent to, at any rate, external cancer. In the breast, if a line be drawn horizontally across the organ through the nipple, every cancer I have seen (with few exceptions) has been situated in the upper segment, or at any rate not below the line. That is due, in my opinion, to the edge of the corset pressing against and causing continual irritation in the overlapping part of the breast. The only exceptions have been in old women, and in them the cancer has been situated in any part.

The cells of chronic inflammation are indistinguishable microscopically from cancer cells. The change into malignancy seems to be a gradual process and taking possibly a considerable length of time, this being due to the amount of resistance on the part of the tissues. Hence in feebly resisting tissues one gets the rapidly growing cancers sometimes seen. Until that resistance is overcome malignancy does not occur. If the inflamed area is removed before resistance has ceased, or even very soon after, there is an end of the matter. By resisting power I mean the ability to expel or absorb the invading cells. If after an operation for chronic inflammation or its sequels, such as an abscess, some of these invading cells are left behind and resistance has ceased, then a malignant growth may arise. A woman, aged 41, came to me in October, 1908, with a chronic abscess of the breast. She had had several children and had suckled her last baby up to a few months before. The abscess was opened, it healed up, and she went home. She returned in January, 1909, with a suspicious hardness deep down in the breast exactly at the site of the former abscess. The organ was removed, and a scirrhus of

the size of a small marble was found. The centre of the growth showed the usual stroma, but at the growing edge the cells were losing their round shape and were becoming elongated. Further away they had their usual round formation, exactly like the cells of chronic inflammation. Is it not reasonable to assume that this elongation is taking place at the seat of least resistance, and that these elongated cells will ultimately form the stroma of the cancer as it extends? At the time of the formation of the abscess the inflammatory cells were present, and doubtless were not all removed in the subsequent treatment. These, though not malignant then, developed malignancy later. I am convinced that if all the cell-ridden area had been excised there would have been no cancer. It seems that in any tissue the continued presence of these leucocytes which the tissue is unable to rid itself of makes for malignancy. When does the pre-malignant stage of cancer cease? I should say when these chronic inflammation cells are losing their round shape and becoming elongated. Resistance on the part of the tissues has become feeble or entirely ceased, and malignancy, or at any rate the commencement, has developed. The position may be stated thus: after remaining in the tissues for an indefinite period these cells, if not removed, elongate and become malignant. Repeated attacks of inflammation are not sufficient to produce this—they must be attended by retention of the cells in the tissue and gradual loss of resistance thereof. For instance, even after repeated attacks of gastritis in the drunkard cancer is rare, because probably these cells are absorbed without any delay. Showing the intimate relationship between cancer and chronic inflammation, if any source of irritation be removed before malignancy has set in the parts involved will most probably recover.

I am, Sir, yours faithfully,

H. LYLE,
Senior Surgeon to the Liverpool Hospital for Cancer and Skin Diseases.

Liverpool, July 26th, 1911.

ARTIFICIAL PNEUMOTHORAX IN TREATMENT OF TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—I was very much interested in the important communications by Dr. C. Lillingston, Dr. L. Colebrook, and Dr. S. V. Pearson and Dr. A. de W. Snowden printed in THE LANCET of July 15th. The paper by Dr. Lillingston was most complete, and he seems to have mentioned almost all the possible misfortunes as well as the methods of safeguarding the patient, while the treatment is being carried out according to Saugman's technique. But I should like to discuss one point which surprised me not a little. He describes rather contemptuously the method of Brauer and Spengler as either obsolete or at any rate almost useless. About five years ago I spent nearly two years at Davos-Platz and Davos-Clavadel and heard much of this wonderful operation of Brauer's and saw some of his cases, and they seemed surprisingly successful.

Hearing, as Dr. Lillingston remarks, that the English cases in Davos could not return home last summer because there was no one in England capable of carrying on the treatment, I, at the request of sundry patients and doctors, went out last winter to Clavadel and there learnt all I could of these new developments of the artificial pneumothorax treatment. I have both assisted at and performed the initial operation and the after-fillings a good many times now, and from my comparatively small personal experience and the very considerable number of cases whose notes I have studied I have come to the conclusion that the initial open operation as performed by Brauer is not very dangerous, and that the dangers of pleural reflex, air embolism, sepsis, and so on are greater at the time of the earlier after-fillings, especially when Saugman's needle is used, as it invariably is used by Spengler, Frey, Neumann, Noble, and the other practitioners at Davos.

If this conclusion of mine is true, it seems to me that a combination of Brauer's initial operation, with the use of a fine trocar and cannula fitted to Saugman's needle-mount for the after-fillings, should make the procedure in the majority of cases free from the risks mentioned in Dr. Lillingston's paper. I had such a needle made for me by the Holborn Instrument Supply Company. Dr. Brauer and Dr. Spengler in their latest work on this subject describe some 113 cases of their own. In 26 it was not possible to make a pneumothorax owing chiefly to extensive adhesions, but of the other 87 patients, all having severe disease and going downhill before the operation, 65 per cent. were very favourably influenced by the operations, and in each case the prognosis is now either good or very good.

The technique needs great care on the part of the operator and his assistant, but there seems little doubt that the induction of an artificial pneumothorax is of the greatest use in the treatment of some apparently hopeless cases of advanced pulmonary tuberculosis.

I am, Sir, yours faithfully,

Brechin-place, S.W., July 24th, 1911. HERBERT RHODES.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.

To the Editor of THE LANCET.

SIR,—Owing to certain difficulties arising out of the management of this hospital, and the manner in which the grievances in respect of such were dealt with by the board of management, we, the undersigned members of the medical staff, felt compelled, acting under legal advice, to take a certain course. As a result of this action we were called upon to resign our appointments by the board within seven days, and, declining to do so, we have received imperative notice of dismissal, and have ceased to have any connexion with the said hospital. We shall take steps to lay the facts of the disabilities under which we suffered before the profession, and also before certain medical and lay hospital authorities, and in the meantime trust that, should the vacancies upon the medical staff be sought to be filled by the board, would-be candidates, before applying for our late appointments, will make themselves cognisant of the conditions which prevail, and have prevailed, at this hospital both now and in previous years.

We are, Sir, yours faithfully,

ALFRED EDDOWES.
AGNES SAVILL.
G. W. DAWSON.
L. F. KNUTHSEN.

July 17th, 1911.

FRENCH MEDICAL OPINION ON THE BRITISH INSURANCE BILL.

(FROM OUR SPECIAL COMMISSIONER.)

Paris, July 26th, 1911.

THE members of the medical profession in France, and especially those who are members of militant medical unions, are watching with great interest and not a little anxiety the fate of Mr. Lloyd George's Insurance Bill. To them the paramount question is the free choice of the doctor. There must, they say, be no State medical functionaries, and no monopolies created for disposal by the politician who has influence over voters. It is as a medical practitioner and not as a successful canvasser at election times that patients should be able to select their medical attendant. The new Health Committees that are to decide how to carry out the legislative provisions are not likely in French opinion to be neutral in politics. Theoretically, all elected administrative bodies in England, except the two Houses of Parliament, are supposed to have no politics. A municipality is constituted merely for local purposes, though it is often elected now on the lines of the political parties; and this is also the case with less important bodies, such as, in England, the boards of guardians. What, then, is going to be the politics of the proposed Health Committees seems to our French neighbours a vital point. Are they likely to be free from all political bias? Are there, indeed, administrative bodies anywhere that can be considered as free from political bias? Medical men are not themselves absolutely free from political predilections, and their full representation on the committees would not alter this danger. When, in answer to these curious criticisms, I confessed that it seemed to me possible that the medical profession in England, if polled, would show a Conservative majority—a view which I knew many medical men would not agree with—the retort was immediately made that this might account for some of the

opposition to the Bill. I protested to my questioners that every effort had been made, on the contrary, to exclude politics from the discussion of the Bill, and that the Conservative party, by the voice of its leaders and in its journals, had expressed its approval of the general principles of the Bill. The idea of political bias was firmly rooted in their minds, and they continued to point out that a medical adviser must not be imposed on a patient because he had found favour in the eyes of some authority or other. If such authority is not guided in its choice by political motives, it is likely to be influenced by family or personal interests; in fact, by any number of considerations save the one and only reason that should govern the choice of the medical attendant.

The French View of Vested Interests in Club Practice.[1]

The only means of excluding influences that should not be brought to bear was, from the French viewpoint, to allow the medical practitioner to appoint himself. This, I explained, was exactly what would happen in the majority of cases. Any fully qualfied practitioner who was willing to do the work could inscribe his name on the panel, but there remained a minority of cases where the patient would not be free to send for the practitioner he might prefer. There were the medical men at present employed at regular salaries by the Friendly Societies, and these salaries were likely to be treated as vested interests which must not be disturbed. The same difficulty has arisen in France, though the term "vested interests" does not exist there. It is replaced by the very appropriate expression "acquired situations" (*situations acquises*). Dr. M. Vimont recently published an eloquent protest against the excess of consideration shown to "acquired situations" under the contract system. In the *Concours Médical* he explains that he has himself served as the medical officer of various Friendly Societies and quite understands the anxieties of these poorly paid practitioners. Nevertheless, he questions whether their position as the salaried medical officers of mutualist organisations or Friendly Societies can be considered as a vested interest. He draws a picture of the young practitioner remaining at home, depriving himself of holidays for fear of losing a patient, devoting himself with the utmost assiduity to the few patients who send for him, till at last, after much privation and many efforts he wins a good name and establishes a practice. This, indeed, is an "acquired situation," and is due entirely to personal effort and merit. But by-and-bye, though he has in no wise modified his manner of treatment and has been and is just as successful, his patients leave him one by one. They leave him because they join the Friendly Society of the industry in which they are engaged. At first, however, he continues to attend to wives and children, but in course of time even that fails him, for the Friendly Society extends its field of action and takes in the women and children as well. Here, then, is a vested interest destroyed by a Friendly Society, which imports a medical officer and makes him attend patients on charity terms with the aid of an elaborate system of advertising and touting. Then, as a climax, when a reform is proposed, it is urged with due solemnity that respect must be shown for the vested interest of the Friendly Society's medical officer; the vested interest of the very man who has destroyed by unfair competitive methods the best, the most worthy, form of vested interest that can possibly exist.

The "Medical Monopoliser."

The "medical monopoliser," as he is called in France, is one who acquires a vested interest in medical practice not by reason of his personal efforts and successful experience among the sick and the suffering, but by going about hat in hand soliciting a post, bringing outside influences to bear, getting people who have nothing to do with medical practice to recommend him to the lay committee managing a Friendly Society. He surrenders his personal independence, he consents to become the salaried servant of a number of persons who know nothing about the medical profession or medical matters, he accepts payment that is much below the prevailing custom, and thus damages not only his own interests—which Dr. Vimont holds him at liberty to do—but also the interests of all his colleagues, which is most unfair and most reprehensible. He allows himself to be imposed, to be forced, upon a sick man, instead of waiting until, as a consequence of the honourable exercise of his profession, the sick man is inspired with confidence in him and voluntarily sends for him. On one side we have the medical practitioner who has acquired a practice by his own skill, science, and hard work; on the other is a practitioner who owes his practice to the fact that he was appointed by a lay committee, and was willing to violate the fundamental principles of the profession of medicine. Where rests the vested interest? Does it rest with the independent practitioner or with the practitioner who has sold himself?

Proposed International Action in Regard to the Bill.

Mr. Lloyd George, on more than one occasion, has expressed his approval of the principle of free choice of medical attendant by the patient. But if the wage limit is to be maintained at £160 a year and the payment is not to be much higher than 6*s.* a year, then it seems quite obvious that many practitioners will suffer, and suffer severely, in their pockets. In fact, their vested interests will be affected.

The French practitioners with whom I discussed this matter viewed the prospect of British legislation setting such an example with little short of terror. Such a bad precedent, they said, would be extremely injurious to their British colleagues, and would check the campaign now successfully in progress in France against similar abuses. Would it not be possible, I was eagerly asked, for some representative British and French medical men to meet and draw up a joint manifesto? The *entente cordiale*, surely, was not a mere empty sound—a pretty sentiment with nothing practical about it. Here, in France, the economical difficulties besetting the medical profession were almost identical with those obtaining in England. Would it not lend greater weight to the demands brought forward if they were simultaneous and similar in both countries.

An Opportunity for Reform.

The great benefit of the proposed law is the panel, but only, my French friends say, if it is universally applied. It is bad enough that medical monopolies should have been created by Friendly Societies and medical aid clubs of all sorts, acting as private organisations established by private enterprise. Against such a procedure medical men have formed militant unions and have collected strike funds, and there have been many medical strikes throughout Europe. The Governments may plead that where freedom of association exists they are not responsible for what these associations may do. But Governments are responsible for the laws they present to Parliament. If, under private enterprise, a mischievous and bad system has grown up, a system that has been condemned by at least nine out of every ten medical practitioners in England, France, Germany, Belgium, and in fact throughout Europe, it surely is not the rôle of any Government, seeking to legislate for the public good, to give legal sanction to abuses. The Friendly Societies and medical aid clubs must no longer be allowed to impose upon their members such medical men as their managing committees may choose to appoint, or to oppress their medical officers. The Health Committees to be created under the proposed law will be able to see that the panel is open to all who are properly qualified. The club doctors of good professional repute should not lose anything by the abolition of their function as club doctors. They have only to put their name on the panel and their patients will continue to send for them just as before. If, on the other hand, they have not been acceptable to the patients, the law should have no right to interfere with the liberty of the patient and force him to accept medical attendance he does not wish to have. In Germany and in France, where strenuous resistance is being organised against such an abuse, its legal sanction by a British law would be looked upon as a retrograde measure likely to have an injurious moral effect throughout the continent.

[1] The article was written, of course, before the agreement was come to in the House of Commons on Clause 13 of the National Insurance Bill.

SEVENTH INTERNATIONAL CONGRESS OF DERMATOLOGY AND SYPHILOLOGY.—This congress will be postponed from September, 1911, to the middle of April, 1912. This delay is due to the fact that many of the foreign committees have found the month of September very unsuitable for their members. Previous references to this congress were made in THE LANCET of May 20th, 1911 (p. 1395) and Sept. 17th, 1910 (p. 921).

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Extensive Outbreak of Ptomaine Poisoning at Bacup and Elsewhere.

AT Whitsuntide a severe outbreak of what seems to be ptomaine poisoning occurred in the Rossendale Valley of Lancashire, whereby over 150 people were affected, in some instances whole families being rendered seriously ill. Bacup was the chief centre of trouble and had the largest number of cases. The cause is alleged to be eating of potted meat at a time when the weather was such as to conduce to the formation of irritant substances which bring symptoms like those of ptomaine poisoning. Five such cases are reported as having ended fatally at Bacup. Three cases occurred at Oldham, two of the victims having eaten some potted meat at a friend's house in Bacup; while a third who had visited Bacup was reported to be suffering from ptomaine poisoning. Over 50 persons in Chesterfield required medical aid owing to a virulent attack of ptomaine poisoning, while a somewhat similar outbreak occurred in Over Peover in Cheshire after the Coronation festival, whereby about 40 persons were attacked with symptoms pointing to ptomaine poisoning.

Manchester Education Committee: Report on Manchester School Children.

From the report of the Manchester Education Committee I learn that the number of elementary school children at the end of last year was 121,087, and of these 7445 were under the age of five, a number equal to a percentage of 6·2 in Manchester schools, as compared with 6·9 in those of England and Wales generally. The number of scholars over 12 years of age was 22,853, and that between 14 and 17 years of age 40,000. The number continuing their education, either in evening or secondary schools, did not exceed 15,000, so that 25,000, or over 60 per cent., were attending neither day nor evening schools. It appears that for England and Wales generally over 74 per cent. of scholars do not continue their education either at day or evening schools. It is gratifying to find that since attention has been directed by the medical officer to physical defects on the part of the children, heed has been given to his suggestions in the case of 92 per cent. of the total number. As usual, a large number of children were found to be suffering from defects of sight. Many of the parents manifest a strong antipathy to their children wearing spectacles. This may in part be explained by the fact that the wearing of spectacles is considered to lower a child's value as a working unit when it comes to leave school. It may also be partly due to the reluctance to pay for the glasses. During the year 273 children were supplied with spectacles. It is stated that Jewish children, as a rule, have very bad sight, which, it is suggested, is partly to be ascribed to their having to learn Hebrew; for only the boys are taught Hebrew, and it is they who suffer much more than the girls from defective vision. Jewish children are better nourished than Gentile children, and the Jewish boys and girls reach a higher anthropometric standard than Gentile boys and girls. No cases of mental defect were found in nearly 1000 Jewish children, whereas 0 6 per cent. of Gentile children were found to be mentally defective.

British Universities Students' Congress.

About 50 delegates, representing 17 British universities and colleges, assembled recently in the University of Manchester. Amongst other interesting matters discussed was the question of the recognition of British medical degrees in Germany. It was reported that negotiations with the German Government asking it to repeal an ordinance withdrawing recognition to British degrees in the case of candidates for a doctor's degree in Germany had been successful in obtaining redress from all German universities outside of Prussia. Similar negotiations in the case of degrees at Swiss and Austrian universities had met with complete success. The question of the possibility of the interchange of examinations and the recognition of the courses of the various British universities within the Empire was discussed and referred to a committee.

Annual Report of Manchester and Salford Sanitary Association.

The annual report of this association for 1910 has just been issued. Thanks in part to the efforts of the association in regard to the "conquest of consumption," the view is expressed that some of our authorities seem to show a disposition to take action of the kind advocated by the association. The other two subjects which have engaged the attention of the association are the smoke nuisance and the care of the feeble-minded. Again there is a falling-off of revenue. It is truly remarkable what excellent work is done by this association, although the income is only about £90 per year. More might legitimately be expected from a great city like Manchester and an ancient borough like Salford. The cheap series of publications, such as "Health Lectures for the People" (1*d.* each), and leaflets for distribution amongst the community should be better known and funds provided for their distribution.

Opening of the New Extension of Salford Royal Hospital.

Lord Shuttleworth opened the new buildings of the Salford Royal Hospital on July 6th. With this extension the hospital equipment meets the most advanced requirements of medical and surgical science. The increase in beds is from 119 to 209. Lord Shuttleworth recalled the fact that his father was a physician and took an active part in combating the epidemic of cholera which swept over Manchester in 1831. After speaking of the remarkable advances in surgical practice during the last 60 years, his lordship touched upon the extreme desirability of municipal corporations giving themselves most thoroughly to the task of clearing away those places to which the horrible word "slum" was attached. He expressed the faith that the new extension would prove a priceless boon to thousands of the people in the present and in future times. The extension committee collected £50,000 in four years in aid of the hospital.

July 31st.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Liverpool Hospital Saturday and Sunday Funds.

THE joint honorary treasurers of the above-named funds have distributed £10,100 amongst the following institutions: Liverpool Royal Infirmary, £2075; Royal Southern Hospital, £1450; David Lewis Northern Hospital, £1425; Liverpool Stanley Hospital, £775; Liverpool dispensaries, £575; Liverpool Infirmary for Children, £550; Queen Victoria District Nursing Association, £525; Liverpool Eye and Ear Infirmary, £375; Liverpool Hospital for Consumption, £300; Hospital for Women, £300; and St. Paul's Eye Hospital, £300. Other institutions of lesser magnitude received sums varying from £250 to £25. The number of beds contained in the several charities determined the amounts apportioned.

Liverpool Maternity Hospital: "Coronation Year Fund."

In April last the Lady Mayoress made an urgent appeal on behalf of the Liverpool Maternity Hospital, and a "Coronation Year Fund" was opened which realised £2000 odd. Up to last March £10,000 had been raised towards the endowment fund, which Sir William Hartley made conditional on his erecting a new hospital. A promise of £500 has also been made by a lady, provided a like sum is forthcoming from other sources. To facilitate matters Sir William Hartley has now kindly consented to modify his original proposal, and will commence the building of the new premises, which are to be erected on the site of the old almshouses in Cambridge-street, when £15,000 shall have been raised, relying on the balance of the fund being obtained when the edifice is completed.

New Assistant Surgeon at the Royal Infirmary.

Mr. H. F. Woolfenden, F.R.C.S. Eng., surgical registrar to the Royal Infirmary, has been appointed honorary assistant surgeon in the room of Mr. T. C. Litler Jones, promoted honorary surgeon

August 1st.

NEWCASTLE-ON-TYNE.

(FROM OUR OWN CORRESPONDENT.)

The Abuse of Charity.

THE deputation appointed by the Royal Victoria Infirmary, Newcastle-on-Tyne, to visit other hospitals have just issued their report. It states that visits were made to the Leeds General Hospital, Manchester Royal Hospital, and the Liverpool Royal Hospital, and very careful and exhaustive inquiries were made. It has learnt that in Manchester and Leeds especially a real effort has been made to deal with the abuse of charities and the delay in the admission of patients; that in the metropolis these difficulties are less acute than in the provinces, hence less effort has been made to introduce any alteration in the mode of admission of patients. The house committee of the infirmary is understood to be now dealing with this report with a view to framing a scheme of admissions upon it. The main principles of the systems in the provincial hospitals visited are summed up in attempts (1) to admit patients through one channel; (2) to facilitate the admission of patients through the out-patient departments; (3) to bring into some co-relation the various waiting-lists of the honorary staff; and (4) to prevent the admission of unsuitable persons. It is reported that at the inspected hospitals the honorary staff had relinquished their positions as the sole admitting authorities, and have been content with the right to admit a certain number of cases per month; that to carry out the investigations necessary there were in the hospitals paid medical and surgical officers of superior standing to the ordinary house physicians and house surgeons; and that, further, there was in Leeds and Manchester a system of almoners working with the Charity Organisation Society. In Manchester there is, in regard to out-patients, a definite wage-limit per family, above which medical attendance and medicine are not given. It is considered that as the result of this report some similar scheme will be introduced by the house committee in the Royal Infirmary. This question of hospital abuse has been the subject of much discussion in the district. The district is so largely artisan, and the working man contributes, in weekly subscriptions of a penny or twopence, such a large proportion of the income—more than half the total hospital income last year—that it cannot be wondered this question has been hotly discussed from time to time and from several points of view in the last few months. The medical profession of the city and district is exceedingly anxious concerning the trend of affairs and would be glad to see some effective means of checking abuse. Whether the example of Manchester in the direction of a wage-limit will be followed is a great problem; it is to be hoped that it may, but such a point will certainly meet with great opposition from the working-man subscriber, who now avowedly considers the institution as existing for his especial benefit, on the lines of a benefit society, kept up mainly by his efforts; he is entirely unmindful of the original foundation of the charity—"for the sick and lame poor."

The National Insurance Bill.

A deputation of medical men from the Newcastle Division of the British Medical Association has been received by the local Members of Parliament—Mr. Edward Shortt, K.C., Mr. J. M. Robertson, and Mr. Walter Hudson. The deputation was headed by Dr. J. Don, Dr. H. L. Rutter, and Dr. T. Beattie, who spoke at some length concerning the Bill, voicing their wishes for adequate remuneration, a free choice of doctor by the patient, a free voice in the local management of health committees, and the establishment of a local medical committee with statutory recognition for the purpose of conferring with the local health committee. The Members gave a sympathetic hearing to the deputation and promised a full and complete consideration of the points laid before them. Mr. Shortt and Mr. Robertson also received a deputation from the Royal Victoria Infirmary; this was headed by Sir Riley Lord, Dr. G. H. Hume, Mr. R. H. P. Orde (secretary of the infirmary), Mr. Charles Irwin, and Mr. Cairns (of the Northumberland Miners' Association). This deputation dealt with the portions of the Bill which have special reference to hospitals, and mention was made of the endangering of subscriptions to hospitals, while the work of those institutions would be largely increased. The deputation thought there might be some sort of an arrangement by which the Treasury could supplement what was done locally, as was suggested by Mr. Lloyd George with regard to the extension of sanatoria work to women and children.

July 31st.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

University of Bristol.

PURSUING a policy already in effect in the departments of anatomy and physiology, the University has appointed a whole-time demonstrator to assist the professor of pathology, who in addition to his university post holds that of pathologist to the Royal Infirmary.

The Bristol Guardians and their Medical Officers.

Mr. F. C. Morgan, medical officer to the Eastville workhouse, having resigned, the Bristol board of guardians has been considering the advisability of a readjustment of the medical care of their workhouse inmates. Under the present arrangement the medical officer to the Stapleton workhouse receives £250 per annum with a residence, and £20 per annum for the headquarters homes, while the medical officer to the Eastville workhouse has received £250 per annum, with £30 in lieu of residence. The guardians' hospital committee recommends certain changes which aim at placing the work at both institutions under one chief medical officer with an assistant. It is suggested that the senior officer should reside at the Stapleton workhouse, receiving £330 with residence, the assistant officer living at the Eastville workhouse and receiving £100, with board, lodging, and washing, or £140 on condition that he lives close to the workhouse. This magnificent salary is offered for assistance in the case of both the workhouses and the headquarters homes. Its inadequacy was pointed out by Dr. W. L. Christie, one of the guardians, but the proposition was agreed to. Fortunately, the scheme is for 12 months only, and Dr. Christie gave notice to move that the resolution be rescinded.

Compulsory Notification of Tuberculosis.

The Bristol health committee has sent a report to the city council recommending the introduction of compulsory notification of phthisis. There is a system of voluntary notification in force in Bristol, and this, with the compulsory notification of institution patients recently introduced by the Local Government Board, has proved of so much value that it is felt advisable to extend notification till all phthisical patients are included.

July 31st.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Dr. Jessie Macgregor Prize in Medical Science.

THIS prize, which is in memory of the late Jessie Maclaren Macgregor, M.D. Edin., is awarded triennially for original work done in any branch of medical science during the three years preceding the award, and is of the value of £50. The award is in the hands of a body of trustees, consisting of the Dean of the Faculty of Medicine of the University of Edinburgh, the President of the Royal College of Physicians, Edinburgh, the treasurer of the Royal College of Physicians, Edinburgh (to whom applications have to be made), the President of the Royal College of Surgeons, Edinburgh, and three medical women, resident in Edinburgh, to be coöpted by the other four trustees. Applicants must have studied for at least one year at a school of medicine in Edinburgh, and must be either graduates of a Scottish University or holders of the triple qualification. The first recipient of the prize is Agnes Ellen Porter, M.D. Edin., the award being made for work done in the departments of bacteriology and physiology, and especially for research into the precipitative reaction in tuberculosis.

Outbreak of Small-pox in Lochee.

An outbreak of small-pox has occurred at Lochee, involving members of three families residing in the west end.

The first case was that of a man who had been suffering for a few days. The case was diagnosed as small-pox, and the patient was removed to hospital on July 22nd. Two days later another case hailing from the same property was discovered. The patient, in this instance a woman, was on intimate terms with deceased's family, and had assisted them in their affliction. She was also removed to the small-pox hospital at King's Cross, and both families were removed to the reception house. A third case was discovered on the 27th, that of a young woman who resided in the vicinity where the other cases occurred. The first case succumbed on the evening of his admission to hospital; the other cases are doing well. The origin of the outbreak has not been traced. The area in which the cases have occurred is in the open country.

Turriff District Hospital: Annual Meeting.

The annual meeting of the committee of management of the Turriff District Infectious Hospital was held on July 27th. Thirty-five patients have been treated in the hospital during the year ended May 15th last. Fourteen of these were cases of diphtheria and 21 scarlet fever. At the beginning of the year there was a balance of £35 0*s.* 5*d.* and at the end of the year a balance in hand of £29 11*s.* 9*d.* The clerk submitted a statement of the probable expenditure for the current year, which amounted to £494 11*s.* 9*d.*, less balance, leaving £465 to raise by assessment, £347 2*s.* 11*d.* falling to the Turriff district and £117 17*s.* 1*d.* to the burgh of Turriff. The meeting agreed to intimate accordingly.

August 1st.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Dublin Hospitals and the Insurance Bill.

AT a meeting of representatives of the chief Dublin hospitals held last Monday to consider the effect of the National Insurance Bill on the hospitals of Ireland, the following resolutions were carried:—

1. That this conference is of opinion that the National Insurance Bill as introduced into Parliament will, if unamended, have an injurious effect on the income of the hospitals of Dublin.
2. That hospitals and dispensaries by which services are rendered to assured persons should receive the actual cost of the expenditure they have incurred for such services under conditions that will preserve the independence of the voluntary charitable institutions concerned.
3. That Clause 15 be amended so as to provide that hospitals and dispensaries should receive the same benefits as sanatoria.
4. That voluntary hospitals be excluded from contributing under the Bill, or, in the alternative, that power be given to the Insurance Commissioners to pay the contributions of employers in addition to the Imperial contributions in the cases of voluntary hospitals out of the funds at their disposal.
5. That in maternity cases treated in hospital wards the allowance be paid directly to the assured person.

Vital Statistics of Ireland.

The annual report of the Registrar-General for Ireland, just presented to Parliament, states that the mortality-rate per 1000 from phthisis in the years 1907, 1908, 1909, and 1910 has shown a successive decrease—viz., 2·7, 2·6, 2·4, and 2·3 respectively. The marriage-rate shows a decrease of 0·12 per 1000 as compared with 1909, the birth-rate a decrease of 0·2, and the death-rate of 0·1. Of the 101,963 births, 52,103 were of boys and 49,850 of girls. 97·2 per cent. of the children were legitimate, the highest rate of illegitimacy being in Ulster, 3·7 per cent., and the lowest in Connaught, 0·7 per cent. The number of emigrants who left Ireland in the year was 32,457.

Lunacy in Ireland.

The annual report of the Inspectors of Lunatics in Ireland was laid on the table of the House of Commons two weeks ago. The summary of the number of insane under care shows an increase during the year 1910 of 250; the corresponding increase in 1909 was 213. The average annual increase in ten years was 328. The number of insane in workhouses has decreased by 84. The percentage of recoveries to admissions was 36·5, being 1·9 lower than that for the previous year.

The Abbey Sanatorium.

Mr. Robert Hall, medical officer to the Abbey Sanatorium, Belfast, has presented his report for the half-year ending March 31st, 1911. Of the males, 19, and of the females, 11 (total, 30) were discharged as "greatly improved"; 142 (95 males, 47 females) were discharged as "improved"; 29 (16 males, 13 females) left "not improved"; 23 (12 males, 11 females) were "not long enough in sanatorium"; and 64 (43 males, 21 females) died; in other words, a total of 288 patients (185 males, 103 females) altogether were treated during the half-year. Of these, 105 (67 men, 38 women) were married, 35 (18 men, 17 women) were widowed, and the remaining 148 (100 men, 48 women) were single. Of the 185 males, the age-period varied from 5 to 73 years. The age-period 25 to 30 years supplied 26 cases; 25 were between 35 and 40; while between 30–35 years and 40–45 there were 24 each. Of the occupations, 89 were labourers, 24 housekeepers, 15 spinners, and 11 weavers; the others belonged to almost every type of worker. Mr. Hall recommends in his report the building of a large self-contained pavilion to accommodate female patients, the appointment of a second resident medical officer, the erection of a verandah round the front of the hospital, and an inter-telephonic exchange. He draws attention to the constantly arising difficulty that patients suitable for sanatorium treatment show a strong dislike to entering the infirmary lest they should be considered as paupers, yet this course is necessary, because the institution is under the Poor-law system. There should certainly be a broader field of admission by which the consumptive poor could enter this admirable sanatorium without being branded as paupers. The best solution would be for the public health committee of the city of Belfast to take over the charge of the place as the central authority. The Abbey Sanatorium was acquired by the Belfast guardians in the autumn of 1904, and was opened for 40 patients in January, 1905, while at the beginning of 1908 there were 265 beds. It is interesting to note that in 1905 (the year the Abbey was opened) 1116 patients died from consumption in Belfast, in 1906 the number was 1015, in 1907 it fell to 926, in 1908 it was 880, and in 1909 it was 811. Mr. Hall thinks that a wider field of admission to the Abbey would produce still more gratifying results. This sanatorium is an excellent example of what can be done for the Irish consumptive by an intelligent body of Poor-law guardians, aided by an enthusiastic medical officer.

Consumptives in Irish Workhouses.

At a meeting of the Strabane (county Tyrone) board of guardians held on July 25th a resolution was unanimously passed to the effect that separate accommodation for consumptive patients be provided, and that a committee be appointed to prepare a scheme for the approval of the board.

The Royal Sanitary Institute.

The twenty-sixth Congress of the Royal Sanitary Institute has been in every respect a great success. The discussions in all the sections and conferences have been admirable, largely in consequence of the prior publication in book form, obtainable by each member, of the various papers to be read. On July 25th, in the Conference on the Hygiene of Childhood, Sir John W. Byers (the President) delivered the inaugural address on the Hygiene of the Child, with Special Reference to Ireland, to which reference was made last week. Then followed two discussions, the first, introduced by Professor J. A. Lindsay, on the Hygiene of School Life; and the second, introduced by Dr. Alfred Greenwood, on Infantile Mortality in Large Towns. A most interesting discussion, in which several speakers took part, followed on the Dental Hygiene of Childhood, introduced by Mr. George Thomson, L.D.S. On the same day, in the Section of Sanitary Science and Preventive Medicine, the address of the President, Sir Lauder Brunton, Bart., was read in his absence, as we noted last week. A discussion on Sewage Purification and on Purification of Rivers and Estuaries followed. In the same section, on July 26th, Dr. J. King Kerr read a paper on Typhoid Prevention, Dr. W. J. Wilson and Dr. C. Dickson read one on the Viability of the B. Typhosus in Water and its Isolation Therefrom, and Dr. Thomas Houston made a communication on Epidemic Cerebro-spinal Meningitis. In the Conference of Municipal Representatives on July 25th, at which the Lord Mayor presided, Dr. P. Boobbyer read a paper on Municipal Hospitals. On the same evening Dr. Louis C. Parkes gave a popular lecture on the Prevention of Tuberculosis: a National Task. In the Section of

Engineering and Architecture, on July 26th, a paper was read on How a Town Succeeded without a Town Planning Act; and on July 27th, in the Sanitary Inspectors' Conference, one on the Smoke Nuisance and Dairies and Milk Supply. In the Conference of Women Dr. Eric Pritchard read a paper on the State Endowment of Motherhood, which gave rise to a very fine discussion. After this Dr. John McCaw read a communication on the Reduction of Infant and Child Mortality from Measles. Papers were also read on Women in Public Health and on Hygiene and Industrial Employment by Miss H. Martindale, H.M. senior lady inspector of factories; and one by Dr. Elizabeth G. Bell on Babies' Clubs, in which she described very fully these institutions in Belfast, which were greatly commended by Dr. Eric Pritchard. A vote of thanks to the Lady Mayoress for acting as President was carried. In the Conference of Medical Officers of Health Dr. Samuel Agnew read a paper on the Medical Officers of Health in Ireland. On July 29th Mr. P. C. Cowan gave an interesting presidential address at the Conference of Engineers and Surveyors, after which there were papers on the Discharge of Sewage into Tidal Waters, and on the Dust Nuisance. In the Conference of the Port Sanitary Authorities Dr. R. Thomson gave the presidential address, after which Dr. Herbert Williams of London read a paper on Plague Precautions in Reference to the Destruction of Rats, and Dr. W. Hanna of Liverpool read a communication on the Importation of Unsound Food. In the Veterinary Inspectors' Conference Dr. H. O'Neill read a paper on Meat Infection, and described the new Belfast public abattoir. At the final meeting of the Congress on Friday votes of thanks were passed to various local bodies and to the Earl and Countess of Aberdeen. Saturday was devoted to excursions.

Condition of Irish Schools.

In several papers read at the Sanitary Congress last week in Belfast attention was called to the insanitary condition of Irish primary schools. For years past the Board of National Education has been urging on the Treasury the necessity of fulfilling the promise made by successive Chief Secretaries to find funds to improve and maintain the school buildings. In many cases the expenses of cleaning and heating had to be borne by the teacher himself out of a stipend less than that of a policeman. At length the Government is to find funds to pay half the expense of cleaning and heating the schools, the other half being paid out of local sources. There is, however, no provision for the cost of installing heating and ventilating apparatus. The buildings themselves, moreover, are in many districts utterly unsuitable as school premises. "All types of school buildings are to be found," says our inspector, "from the well-equipped modern school down to the wretched thatched cabin by the roadside, or the equally objectionable erection in a graveyard." One can hardly expect a high standard of hygiene from working classes who receive their education in such surroundings.

July 31st.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Diminution of Hydrophobia.

SINCE the first years when Pasteur's discovery of the antirabic vaccine was utilised for the treatment of persons bitten by mad dogs statistics have shown a constant decline in the number of deaths. In the year 1910 the numerical records of the Pasteur Institute, compiled by M. Jules Viala, *préparateur* in the antirabic department managed by Dr. Roux, show that 401 patients had antirabic treatment without any case of death being reported. In the year 1886 the number of persons who after being bitten were treated in the Pasteur Institute was 2671, and among them there were 25 deaths, but in 1896 there were 1308 patients with 4 deaths. Since that time the cases of hydrophobia have diminished from year to year, and the number of bitten persons treated annually at the Pasteur Institute has been under 1000 since 1902. There was 1 death in each of the years 1908 and 1909, the number of patients being 524 in the former and 467 in the latter. Among the 401 cases treated at the Pasteur Institute in 1910 there were 11 foreigners, including 3 of British and 8 of Spanish nationality.

The Physiological Effects of Aeroplane Flying.

The increasing number of aviators and the development of aeroplane flying have given opportunities for making some interesting observations on the physiological conditions incidental to this new method of progression. Several factors have to be taken into consideration. Rising to a great height in the air produces effects similar to those of mountain sickness—namely, giddiness, nausea, and headache; but owing to the rapid transition from a low level to a high one or conversely, the blood pressure if it is altered is not allowed sufficient time to become steady as it can do in mountain climbing; the conditions, in fact, have some resemblance to those of a balloon ascent or of an abrupt descent, and even more resemblance to what is seen in the case of subaqueous workers who are quickly brought to the surface from a diving bell, although in aviation the pressures are very much less. There are also great variations with different individuals, for attacks of mountain sickness and other discomforts due to change of pressure are experienced by some at a height of 1500 metres, while others are not affected until they reach 2000 metres. All the observations that have been made show that the blood pressure is increased, but only to a slight extent because it is counterbalanced by the free access of air which, according to the researches of Langlois, tends to reduce the blood pressure. Other factors to be considered are the duration of the flight and the encountering of difficulties. Nervous fatigue lowers the blood pressure and quickens the pulse. The nervous tension brought about by the necessity for being continually on the alert in presence of dangers has a special influence which varies according to the temperament of the individual. I had an opportunity of examining the aviator Beaumont when he came down from his machine after having won the prize for the European circuit. He was remarkably calm and his pulse-rate scarcely reached 85, but he told me that his great natural composure and his long practice in making ascents did not prevent him from having sensations of emotion and cardiac palpitation in moments of danger. As a general result it may be said that aeroplane flying does not cause any special form of illness. Increase of the blood pressure is the most constant phenomenon, but it is very difficult to collect comparable data from different individuals, because this hypertension is counteracted to a variable extent by such influences as the altitude, the length of the flight, the sensation of danger, and the amount of composure possessed by the aviator.

Dogs in the Medical Service of the Army.

The manœuvres in which the medical department of the army has been engaged with a view to the training of the officers both of the active forces and the reserve have once more shown that dogs may be taught to trace wounded men and guide relief parties to the place where they may be lying. Conclusive experiments have already been made at Nancy, at Rennes, and at Lyons, with the result that these dogs—the so-called *chiens sanitaires*—will henceforth be regularly attached to the service of the French army, and a national society has been formed for the purpose of providing a supply of trained animals. At Vincennes, where the recent manœuvres were held, it was remarkable how quickly a stretcher party accompanied by a trained dog could thoroughly examine every part of an extensive area and carry off soldiers concealed in thickets and under branches in the most difficult conditions. A dog can also work by itself. When sent by its master in a certain direction it finds the wounded man, allows him to take the various articles attached to its collar, and carries his cap back to its master, who fastens a string to the dog's collar and is immediately guided to the place where the man was found. If a cap is not to be had the dog searches with its foot or its nose in the man's pockets and takes a handkerchief, a glove, or some other article which may serve for identification. The dog has a collar to which a bell can be attached, and on its back a piece of cloth fastened to its neck with a strap and marked with the Geneva Cross; it also carries a cloth pocket. Retrievers are preferred to dogs which bark and may thereby give much trouble. The qualities chiefly desired in a *chien sanitaire* and developed by training are a keen sense of smell, absolute obedience to

orders, endurance, and especially gentleness so as not to alarm a wounded man. The presence of these qualities was universally recognised in all the dogs at the manœuvres. For those which are to be used in the French army the Minister of War has ordered a military kennel to be established at Fontainebleau, under the management of Captain Tollet. Another kennel was some time ago constructed at Auxerres and proved very successful. This work is very valuable under the conditions of modern war, both in Europe and in the colonies. The first requisite is the relief of the brave men who have fallen in the defence of their country. If left a long time on the battlefield they are liable to be attacked by birds of prey, and in colonial expeditions they have sometimes been mutilated by returning natives. Modern methods of fighting, the movement of troops over considerable areas during a battle, the long range of modern rifles and artillery, and night fighting make ambulance work very difficult. The number of missing men is always considerable, because picking up the wounded during an action becomes less and less possible. At Rezonville there were 1367 killed and 5472 missing, while at Saint-Privat there were 1146 killed, 6709 wounded, and 4420 missing. Some of these have been wounded men who dragged themselves into sheltered places and died there without receiving any help. The trials which have been made with the *chiens sanitaires* have shown the importance of keen scent for them whatever may be their breed, whether pedigree or not. Their work is of a kind not unlike that of the dogs of the *hospices* of the Great Saint Bernard which rescue persons who have sunk in the snow.

The late Dr. Charles Nélaton.

M. Charles Nélaton, well-known as a hospital surgeon, has just died from embolism at the age of 60 years. A son of Dr. A. Nélaton, who was a member of the Institute and surgeon to the Emperor Napoleon III., he walked in his illustrious father's steps. In 1876 he became *interne des hôpitaux*. In 1880, when he was admitted doctor of medicine, he wrote a thesis of some celebrity entitled, "Effusions of Blood into the Pleuræ after Injuries." In the following year he competed for and obtained the position of surgeon to the Paris hospitals, and in 1889 he became *agréyé* in the Paris Faculty of Medicine. Some of his works highly valued by specialists included "Tubercle in Surgical Affections," "The Relations of Injuries and Heart Disease," "The Causes of the Irreducibility of Old Dislocations of the Hip-joint," and "Non-malignant Tumours of the Bones." In concert with his colleague, Dr. Ombredanne, he wrote treatises on "Rhinoplasty" and on "Autoplasty." He was vice-president of the Surgical Society. His death is a loss to the Hôpital Boucicaut, where he gave many proofs of his professional skill and his kindly disposition. Of unassuming personal character, he will be remembered as a man of eminence in his profession, and one who would have probably accomplished much more if his life had been prolonged. His goodness of heart was well shown by his self-denying behaviour at a competition in which he had done well at the examination and was certain of coming out first. His success, however, would have entailed the defeat of another candidate, an excellent man less happily circumstanced than Nélaton, who retired from the competition so as not to stand in the other's way. Incidents of a similar kind were frequent in Charles Nélaton's life, and caused him to be highly esteemed by the members of his profession who are now mourning his decease.

July 31st.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

The Diet in Epilepsy.

AT a recent meeting of the Budapest Royal Medical Society Dr. Donath read a paper on the above subject. He said that the directions for diet in cases of epilepsy were usually limited to the avoidance of indigestible articles of food and the avoidance of stimulants. Useful, no doubt, as far as they went, such directions could not be regarded as adequate or commensurate with our knowledge of the deleterious influence of certain articles of food on an organism prone to epilepsy. It had long been held that a diet too rich in albuminoid constituents was harmful to epileptics. Clinical observation had not always confirmed the validity of this view, and, struck by the contradictory nature of the results, Dr. Donath had undertaken a series of observations. He placed groups of epileptic patients on a strict milk diet and a meat diet respectively, and after six weeks he failed to detect any noteworthy effect of either regimen upon the number of attacks or the general health of the subjects. Incidentally, he found that the suppression of chloride of sodium reduced the frequency of the attacks, but at the expense of the general health, marked loss of weight and strength resulting. Alcohol in moderate quantities he found to be devoid of injurious action. The fact that meat does not appear to be injurious to epileptics suggests the desirability of reconsidering the views on which this article of food has been placed under a ban. There can be no lack of opportunities for carrying out the necessary observations, and advantage might be taken of these selfsame observations to study the influence of quantity, as well as quality, of food. Obviously, no hard-and-fast rules can be formulated in this direction, for in epilepsy, more perhaps than in other diseases, it is the patient who requires treatment rather than the disease. What is required are general rules, to be adapted to individual cases with due regard to the constitution, temperament, and habits of life of the sufferer.

The Spitting Nuisance.

At a meeting of the Budapest city council held to consider certain proposed extensions of municipal powers, it was proposed, among other things, to add the following clause with reference to expectoration in public conveyances and on the side-walks of the streets:—

> Any person who, after being cautioned by a policeman or by any officer in uniform of the corporation, expectorates on any public footwalk, or who, after being cautioned by the conductor or any fellow passenger, expectorates in, on, or from any public conveyance, shall be liable to a penalty not exceeding 200 crowns (£8 6*s.* 8*d.*).

After a considerable discussion, lasting over an hour and a half, a vote was taken, and the clause was adopted by 52 votes as against 33.

Jews and Drunkenness.

Dr. Imre Dóczy, in his work on "Alcoholism," claims that Jews under every condition of life are invariably sober. He thinks that this is not because they resist temptation, for as a race they are not particularly given to austerity, but because deep indulgence is disagreeable to them. He has made inquiries respecting the drinking habits of the Jewish people in Hungary, Russia, and England. So far the evidence he could obtain has quite substantiated this assumption. One medical man whose practice is made up in great part of Jews informed him that during the last 10 years he had only once met with a drunken Jew, and in that case the Jew, as regarded his general manner of life and attitude to the Mosaic ritual, was a "renegade." Dr. Dóczy now intends to investigate why the Jews, though exempt from alcoholism, suffer so often from nervous diseases and insanity, which diseases are to a considerable extent consequential on alcoholism.

July 20th.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

"Death to the Doctor."

"*Morte al medico!*" Such is still the cry of an ignorant, infuriated populace in various provinces of Italy—a cry *motivé* by the fear that in taking the precautions dictated by the Board of Hygiene in presence of enteric disease the local medical authorities were actually courting, if not causing, the epidemic which they were striving to keep at bay. Not only in Sicily, with its chronic *analfabetismo* and superstition and its prompt recourse to personal violence, but within the Roman Province, at the much-frequented bathing resort of Nettuno, the medical officer, no less a man than the delegate of the Red Cross, Dr. Moscioni, was brutally assaulted and maltreated in the exercise of his humane mission. Called to the bedside of a boy *in articulo mortis*

from gastro-enteritis, he endeavoured to persuade the father and mother with their three daughters to accompany him to the local lazzeretto for medical examination. The women consented but the father refused. While Dr. Moscioni was expostulating with him and had even won his assent a crowd gathered before the house and intercepted the doctor, the paterfamilias aforesaid, and the hospital attendants on their way to the lazzeretto. They even tried to enter and remove the dying boy whom they regarded as a victim of the doctor's "arte malefica." But the doctor, the attendants, and the father were beforehand with them, and getting inside locked the door in their face. Savage cries of "A morte! a morte!" ("Death to him! death to him!") followed by volleys of stones, made the position desperate, when a member of the public force, knocking at the door, asked the doctor what he proposed to do. "Remain in the house till the crowd dispersed," was the answer. But the crowd was increasing every minute, and the cannonade of missiles was breaking through the *persiane* (wooden window shutters) when suddenly a man forced his way through one of them, but was stopped by the doctor's levelled revolver. By this time the boy had expired, and the delegate reinforced with a company of carabineers got the doctor out of the house and made a way for him through the crowd. But the shower of stones was redoubled, and the doctor, struck on the breast and on the head, again drew his revolver, but before he could use it got a blow in the face which stunned him and drew blood. At length a tramcar, passing opportunely, picked up the doctor and his escort and put him down at Porto d'Anzio, where he was at once attended to in the local lazzeretto. Such from Dr. Moscioni's own lips is the narrative of what befel him in the discharge of his duty in the suburbs of Rome in the year of grace 1911—the fiftieth of Italy's unity and independence! Even as I write news arrives of an outbreak at Salerno, seat of the once famous medical school, where the fishing population, infuriated at the restriction imposed on the sale of oysters, mussels, and other "frutta del mare," assailed the town hall and the sanitary office with such violence that the local carabineers had to be reinforced with troops of the line before the civic magnates, municipal and medical, could regain their homes in safety. And all this in anticipation, if not in the actual presence, of cholera—an invader which, through tardy precautions, this time last year wrought incalculable loss to Italy's best interests, financial and social. Well may the distinguished publicist Signor Luigi Lucatelli indite a jeremiad on the situation under the title of "Italia Scellerata" (Italy under a curse).

The Health of the Pope.

On July 20th the funeral service in the Sistine Chapel on the anniversary of Leo XIII.'s death was honoured by the presence of His Holiness Pius X., assisted by a distinguished representation of the Apostolic College. It was remarked that the Holy Father appeared greatly fatigued and mentally as well as physically depressed. The day, however, was one of those in which the sirocco prevails, well described as "wind without air, heat without sun, and rain without freshness." This, no doubt, explains in some measure the exhaustion of the septuagenarian pontiff; but it is observed that each successive summer he is less able to stand the subtropical heat. He misses, so say his familiars, the mountain breeze from the Rhaetian Alps, and

"The sea-pulse of the still lagoon."

Apart, however, from a recurring pharyngeal congestion and occasional attacks of gout, his health is not such as to warrant the alarming reports recently put in circulation.

Reafforestation.

The appalling destruction of sylvan growth in Canada, and the forest fires witnessed in the British Isles as far north as Perthshire, revive interest in a theme of more or less perennial interest to all Italians—the preservation of what little woodland remains to them and its renewal by plantation. At Turin, on August 28th, there will be held a "Congresso Forestale" at which the chief authorities on reafforestation will take part. The last congress of the kind was held at Bologna and evoked discussions which will have an even greater relevance in this the "Cinquantario" of the Third Italy.

July 27th.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

Cholera in Constantinople.

MOST contradictory rumours as to the actual state of the epidemic of cholera in Constantinople have been circulating. These rumours still continue to agitate not a little the public mind. There are many here who firmly believe that there is no such thing as cholera in Constantinople at present. I have met with medical men who ridiculed the idea of the reappearance of the scourge, and who spoke of certain diseases simulating cholera. They thought that the alarm shown by the public and the medical authorities was quite unwarrantable. "True enough," they said, "there is cholera in the provinces spreading to an alarming degree, but it has not revisited our city this time." The medical authorities, however, from the first took a very different view. Personally, I think that quite a large number of sporadic cases have occurred in different quarters of the metropolis, and that the epidemic still exists and is spreading, though in a milder form. I myself have attended one or two fatal cases, and there was no mistake as to what the malady was; it was genuine cholera asiatica. A special commission under the presidency of Rifaat Pasha, the Minister for Foreign Affairs, met the other day in the Grand Vizierate to discuss the necessary measures to be taken in order to stem the progress of the epidemic in the provinces as well as in the capital. The scourge is occasioning great ravages, especially in the harbours along the southern shore of the Black Sea, and also in some ports of the eastern part of the Sea of Marmora. The Sanitary Office has decided to form different local commissions in various quarters of the city and outside of it, including also municipal medical men, and to subject to the necessary medical examination all the passengers coming from places contaminated by cholera, such as Smyrna and Samsoun. The municipality of Constantinople has taken a number of preventive measures. For instance, medical men will visit this week all the druggists' and chemists' shops to see that each has at ready disposal the required remedies, and that no exorbitant prices are charged for them. These physicians will also visit houses, public establishments, stables, and other such places, to ascertain that the regulations for thorough disinfection have been adhered to. It is intended severely to punish any case of negligence. In some parts of the city and in the suburbs disinfection is carried on by men employed by the municipality itself. A special council has been instituted for the purpose of attending to sanitary matters in the army. The director of the Military Medical Faculty will be a member of this council, and its president will be Dr. Witting Pasha, the chief of the Faculty of Gulhaneh at Stamboul. One or two factories along the Golden Horn have been shut by the authorities because of the very disagreeable smell they were emitting which permeated the whole neighbourhood. The disinfection of Stamboul is being carried on in an especially energetic manner. Houses, bakeries, baths, and coffee houses are visited daily. The proprietors receive certificates testifying that all the prescribed sanitary injunctions have been carried out. From Sophia, the Bulgarian capital, comes the news that cholera has made its appearance in that city. Bucharest also is said to be visited by the scourge. The Hygienic Commission for Hedjaz, which is under the presidency of the Minister of the Interior, has engaged, according to the local newspapers, five medical men, who will be sent to settle permanently in the cities of Mecca, Medina, Djeddah, &c. Eight physicians more will visit these places only during the season of pilgrimage. In Mecca two field hospitals adapted for use in hot latitudes have been erected lately. It has also been decided to construct a third hospital on the same lines in the new military barracks.

Cholera and Malaria at Bassora.

Fleeing from the scourge of cholera which is raging in a terrible fashion at Bassora, several thousand Jews have gathered at what is known as the Tomb of the Prophet Ezra, on the banks of the river Tigris, five kilometres from Bassora. There the unfortunate people spend their time in lamentation and prayer. The hygienic and sanitary conditions among them are exceedingly bad and the rate of

mortality is very high. There is no medical man on the spot and none would volunteer to visit it from the neighbouring places. The Jews suffer not only from cholera, but also from the ravages of malarial fever, which is raging there in consequence of the numerous extensive marshes. A French paper bringing this news urges the Ottoman Government to send speedy medical assistance.

Lack of Medical Men.

In the provinces of Asia Minor there are many extensive localities and districts where not a single medical man can be found. One can easily imagine, therefore, the bad sanitary conditions under which the population in those places lives, especially in time of epidemic. Thus typhoid fever was raging lately in Dersim, where people were dying by dozens, but in spite of the governor's efforts no medical man was to be had. Only after the death of a Turkish notable and of his wife did the authorities decide to send out a medical man.

July 28th.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—**At the First Professional Examination held on July 17th, 18th, 19th, 20th, and 21st the following candidates were approved in the under-mentioned subjects:—**

Chemistry and Physics.—Leslie Graham Blackmore, Middlesex Hospital; Philip Audley Brown, Brighton Municipal Technical College; George Henry Kelsey Burge, Westminster Hospital and King's College; Charles de Frias, London Hospital; David Hamilton Derry, Royal Albert Memorial College, Exeter, and St. Bartholomew's Hospital; Gerald Gordon Drummond, St. Thomas's Hospital; Cyril Bowdler Henry, Sheffield University; Charles Guy Hitchcock, London Hospital; Russell Walbancke Hodgson-Jones, Manchester University; Harold Reginald Wessen Husbands, Bristol University; Claude Stewart James Kearney, St. Bartholomew's Hospital; Sidney John Liddon Lindeman, St. Bartholomew's Hospital; Marie Gertrude Gwendoline Calvert Link, South Western Polytechnic; Guyon Lynden-Bell, King's College; John Edward Carbery Maguire, St. Bartholomew's Hospital; Rodney Honor Maingot, St. Bartholomew's Hospital; George Edwards Mullins, Birmingham University; Sinnethamby Muttiah, London Hospital; Alfred Samuel Woolaston Pearmund, Guy's Hospital; Frederick Porter-Smith, St. Thomas's Hospital; Edward Austin Prichard-Evans, University College, Cardiff; Edmund Douglas Richardson, Charing Cross Hospital; John Rowland, St. Thomas's Hospital; Percy Gunn Russell, Portsmouth Municipal College; William Henry Sarra, London Hospital; Robert Gordon Simpson, Plymouth Technical Schools; John Bevil Grenville Skelton, London Hospital; Denys Munro Smith, Bristol University; James Randolph WillianStephens, Manchester University; Arthur Alward Watkinson, Charing Cross Hospital; Frederick Langton Webster, Manchester University; Nathan Judah Wigram, Sheffield University; and William Edwin Wilson, St. Bees' School and St. Bartholomew's Hospital.

Chemistry.—Reginald George Joseph Charlesworth, Charing Cross Hospital; Cyril Gould, University College; Roy Dyson Langdale-Kelham, University College; Samuel Durham Lodge, Leeds University; George Samuel Bousfield Long, Guy's Hospital; Roy Bingley Pullin, St. Bartholomew's Hospital; Gerald Richardson Sharp, London Hospital; William Walford Salisbury Sharpe, St. Mary's Hospital; Arthur Sunderland, Charing Cross Hospital; and Percy Ward, Sheffield University.

Physics.—Basil Edward Barnes, Birmingham University; Kenneth Leslie Bates, Guy's Hospital; Hugh Stanford Bryan, London Hospital; Frank Philip Gilbert de Smidt, London Hospital; Herbert Mervyn Drake, St. Thomas's Hospital; John Eric Evans, Liverpool University; Melville St. Clair Hamilton, Charing Cross Hospital; William Norman Harrison, St. Mary's Hospital; Wilhelm Otto Holst, Middlesex Hospital; George Hubert Howe, Guy's Hospital; Henry David Llewellin Jones, St. Mary's Hospital; Theodore Louis Kan, King's College; Guy Kinneir, Tonbridge School; William Ulic Desmond Longford, St. Bartholomew's Hospital; Jose Miguel Madariaga, Buenos Ayres and St. Thomas's Hospital; Lionel Watson Moore, Guy's Hospital; Dudley George Pearce, Guy's Hospital; George Cuthbert Robinson, St. Thomas's Hospital; Henderson Whyte, London Hospital; and Ismail Zaki, University College.

Biology.—Basil Edward Barnes, Birmingham University; George Henry Kelsey Burge, Westminster Hospital and King's College; Joseph Woods Clayton, London Hospital; Dennis Reginald Curnock, Birkbeck College; Charles de Frias, London Hospital; David Hamilton Derry, Royal Albert Memorial College, Exeter, and St. Bartholomew's Hospital; David MacMurray Dickson, St. Thomas's Hospital; George Augustus Norman Dod, Birkbeck College; Herbert Mervyn Drake, St. Thomas's Hospital; David John Evans, University College, Cardiff; Cyril James Gozney Exley, University College; Gloster Tyndall Garraway, University College; Cyril Gould, University College; Russell Walbancke Hodgson-Jones, Manchester University; Wilhelm Otto Holst, Middlesex Hospital; Tudor Philip William John, University College, Cardiff; Mahmood Mahfooz, Cairo and King's College; Harry Millett, Guy's Hospital; Sinnethamby Muttiah, London Hospital; Raphael Neft, Guy's Hospital; Warre Harriott Alexander Pratt, Guy's Hospital; Thomas Francis Reason, Technical College, Swansea; Edmund Douglas Richardson, Charing Cross Hospital; Rupert Idris Rhys, University College, Cardiff; Robert Gordon Simpson, Plymouth Technical Schools; Arthur Dighton Stammers, London Hospital; James Randolph William Stephens, Manchester University; Felix Tagger, Charing Cross Hospital; Donald Carmichael Thomas, St. Thomas's Hospital; Frederick Langton Webster, Manchester University; and Henderson Whyte, London Hospital.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—**At the Preliminary Science Examination for the Licence in Dental Surgery, held on July 17th, 19th, and 21st, the following candidates were approved in the subjects mentioned:—**

Chemistry and Physics.—Gerald Beaumont Ash, Polytechnic Institute; Douglas Arthur Bevis, Portsmouth Municipal College; Reginald Gordon Bradley, Birbeck College; Stanley Bremner, Liverpool University; Charles Reginald Cade, Royal Albert Memorial College, Exeter; Walter Ernest Coe, King's College; Debenham Stuart Coombs, Middlesex Hospital; William John Curtis, Middlesex Hospital; William Robert Davies, Bangor; Clifford Cedric Dixon, Leeds University; Victor Robert Dyke, Sexey's School, Bruton; John Kelvin Sawards, Liverpool University; Raymond Cecil Thomas Evetts, Polytechnic Institute; Harold Mayston Fisher, Battersea Polytechnic; Cecil William Hammond-Williams, Guy's Hospital; Charlie Lewis Hicks, East London College; Harry Austen Hutson, Polytechnic Institute, Philip Everard Jessop, Polytechnic Institute; John Arnold Johnstone, Middlesbrough High School; Leslie Grantham Lunnon, Polytechnic Institute; Harold Armstrong Metcalfe, Technical College, Sunderland; Lancelot Eric Charles Peckover, Brighton Technical College; Geraint Arthur Pennant, University College, Cardiff; Beresford Tom Richards, Derby Technical College; Stephen Archibald Rodda, Wandsworth Technical Institute; Frederick Elliott Smith, Polytechnic Institute; Herbert Leslie Smith, Brighton Technical College; Harold Treleaven, Middlesex Hospital; William Thomas Williams, Liverpool University; and John Clark Yeoman, Birmingham Technical School.

Chemistry.—Henry Hall Buckley, Royal Technical Institute, Salford; William Sutton Campbell, University College, Cardiff; Arthur Hedley Cole, Plymouth Science, Art, and Technical School; Frank Briggs Cullen, University College, Nottingham; Howard Curtis, Hartley College, Southampton; Edmund Dinsmore, Charing Cross Hospital; John Langley Garrard, Guy's Hospital; Herbert Gee, Holt Schools, Birkenhead; William Henry Churchill Gordon, Guy's Hospital; Arthur Helmuth John Miller, Charing Cross Hospital; Fairman John Ordish, Mercers' School; Ernest Bert Parry, Battersea Polytechnic.

Physics.—Frederick James Arbery, Polytechnic Institute; Harry Edward Atkins, Birkbeck College; Walter Pigott Barfoot, Brighton Municipal College; Armin Frank Maximilian Fuoss, Wolverhampton Grammar School; Godfrey Macdona Hick, Bristol University; Bernard Isaacs, Guy's Hospital; Leonard Stanley Pilbeam, Brighton Municipal College; Frank Edwin Rudd, Norwich Technical Institute; and Arthur Herbert Virgin, Bristol University.

UNIVERSITY OF LONDON.—**At the Second Examination for Medical Degrees (Part II.), held in July, the following candidates were successful:—**

Edward Smith Abraham, University of Bristol; William Daniel Arthur, University College, Cardiff; Joe Edward Ashby, Charing Cross Hospital; Leonard Barron Baird, Victoria University of Manchester; Irene Bastow, London (Royal Free Hospital) School of Medicine for Women; Robert Maitland Beath, Queen's University, Belfast; Frank Percy Bennett, St. Mary's Hospital; Geoffrey Andrew Bird, St. Thomas's Hospital; Alice Dorothea Brooks, London (Royal Free Hospital) School of Medicine for Women; Frederick Charles Sedgwick Broome, Guy's Hospital; Marion Mildred Barrow Burt, University of Birmingham; William Burt, St. Thomas's Hospital; Noel St. John Grey Dudley Buxton, University College; Aaron Simeon Cohen, University College, Cardiff; Frederick Hugh Lester Cunningham, St. Bartholomew's Hospital; John Horace Dancy, King's College; Joseph de Silva, St. Mary's Hospital; *Arthur Rawdon Carrington Doorly, St. Thomas's Hospital; Philip Oswald Ellison, St. Bartholomew's Hospital; Georg Arnold Gassman, London Hospital; Henry Little Hardy Greer, Queen's University of Belfast; Cecil Rhodes Harrison, St. Mary's Hospital; *†Henry Julyan Hoyte, King's College; *†Arthur Llewelyn Jones, McGill University, Montreal, and London Hospital; Eric Pierpoint Langley, St. Mary's Hospital; Abraham Stephen Liebson, Guy's Hospital; Oliver Cuff Link, Middlesex Hospital; Geoffrey Trevor Lougborough, St. Bartholomew's Hospital; Norman Peace Lacy Lumb, St. Thomas's Hospital; Ronald Guy Lyster, St. Bartholomew's Hospital; Arthur Griffith Maitland-Jones, London Hospital; Refna Mallet, London (Royal Free Hospital) School of Medicine for Women; *John Ernest Pearce, St. Bartholomew's Hospital; Cyril Eaton Petley, Guy's Hospital; Robert Edward Roberts, University of Liverpool; William Eric Roper Saunders, St. Bartholomew's Hospital and University of Durham; Reginald Hugh Simpson, St. Bartholomew's Hospital; Hector Smith, Charing Cross Hospital; ‡Francis Gerald Augustus Smyth, St. Bartholomew's Hospital; Henry James Drew Smythe, University of Bristol; ‡William Edward Tanner, Guy's Hospital; Charles Hamblen Thomas, St. Bartholomew's Hospital; Naomi Tribe, London (Royal Free Hospital) School of Medicine for Women; Joseph Stephen Wallace and John Glen Wardrop, University College; Thomas Burges Welch, St. Bartholomew's Hospital; Eva Muriel White, London (Royal Free Hospital) School of Medicine for Women; Henry Parks Whitworth, Guy's Hospital; William Bernard Wilson, St. Bartholomew's Hospital; Arthur Graham Winter and Herbert Gregory Winter, London Hospital; William Pridham Wippell, St. Bartholomew's Hospital; Montague Sydney

Woolf, University of Birmingham; and *†James Montague Wyatt, St. Thomas's Hospital.

* Distinguished in Anatomy. † Distinguished in Physiology.
‡ Distinguished in Pharmacology.

N.B.—This list, published for the convenience of candidates, is issued subject to its approval by the Senate.

VICTORIA UNIVERSITY OF MANCHESTER.—At examinations held recently the following candidates satisfied the examiners:—

FINAL M.B. AND CH.B. EXAMINATION.

C. E. Butterworth, Norman Duggan, A. W. Gaye, Harold Heathcote, *A. H. Holmes, *W. H. Kauntze, Mabel E. May, *Jane C. Miller, Manfred Moritz, Lovel Moss, *S. B. Radley, G. E. Sawdon, J. B. Scott, William Stirling, *J. S. B. Stopford, and G. K. Thompson.

Obstetrics.—W. H. Laslett.

Forensic Medicine and Toxicology.—O. R. Allison, Walter Barnes, R. B. Berry, A. G. Bryce, L. T. Challenor, Geoffrey Fildes, A. W. Gaye, Harold Harrison, George Jackson, J. A. Lees, P. H. Midgley, H. G. Peake, L. W. Sparrow, C. F. White, Vera N. Welzmann, and A. G. Wilkinson.

* Second-class honours.

MASTER IN SURGERY.

John Morley.

THIRD M.B. EXAMINATION.

Pharmacology and Therapeutics and Hygiene.—Allan Barrett, F. A. Bearn, J. G. Bennett, E. S. Brentnall, C. H. Crawshaw, H. N. Crossley, H. F. Hutchinson, Eugene Leahy, C. G. Lees, F. L. Newton, W. L. Nicholson, T. P. Robertson, A. V. Stocks, Ernest Talbot, Cornelius Thompson, H. W. F. Williams, and G. W. Wood.

Hygiene.—H. S. Gerrard.

FIRST M.B. EXAMINATION.

Part III., Organic Chemistry and Bio-Chemistry.—H. W. Bennett, C. P. Brentnall, J. D. Byrd, Hitchon Chadwick, Robert Chevassut, J. S. Chorlton, Edgar Granger, J. B. Leigh, H. M. von Mengershausen, J. F. C. O'Meara, John Rigby, H. H. Stones, C. G. Todd, Frank Vause, Bryan Walley, and Richard Willan.

FINAL B.D.S. EXAMINATION.

A. C. W. Hutchinson.

FIRST B.D.S. EXAMINATION.

M. C. Paterson and Aquila Whitehead.

DIPLOMA IN DENTISTRY (FINAL EXAMINATION).

H. R. Ellis, Arnold Gibson, W. F. Gregory, D. M. Lawrie, C. H. Plummer, W. J. Piper, S. G. Ross, Thomas Rothwell, and A. B. Tough.

DIPLOMA IN PUBLIC HEALTH.

M. T. Ascough, Alan Boyle, E. F. S. Green, A. K. Lomas, Agnes J. Maclaren, Edith M. Marsden, C. B. Marshall, R. H. Mercer, Richard Price, W. W. Uttley, and C. F. Walker.

CERTIFICATE IN FACTORY HYGIENE.

Alan Boyle, J. D. Buchanan, Alfred Greenwood, Hugh Lawrie, J. S. Manson, W. C. Rigby, Harold Thorp, and W. W. Uttley.

CERTIFICATE IN SCHOOL HYGIENE.

John Allen, Alan Boyle, J. D. Buchanan, William J. Cox, Alex. Grant, Hugh Lawrie, Harriet McCloghry, and A. H. Norris.

Mr. Judson Sykes Bury, M.D. Lond., B.Sc. Manch. and Lond., F.R.C.P. Lond., has been appointed to the Chair of Clinical Medicine in the University of Manchester. Dr. Bury holds the position of physician to the Manchester Royal Infirmary and was formerly Bradshaw lecturer to the Royal College of Physicians. He has written an important work on clinical medicine and is joint author with the late Dr. James Ross of a treatise on "Peripheral Neuritis."

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following candidates, having passed the necessary examination, have been admitted Fellows of the College:—

R. H. Adams, L.R.C.P. & S.I.; J. W. Killen, M.B., B.Ch., Royal University; A. A. M'Connell, M.B., B.Ch. Dub.; W. F. O'Connor, M.B., B.Ch., Royal University; Miss M. J. Shire, L.R.C.P. & S.I.; and S. B. Surti, L.M. & S. Bombay.

The following candidates have passed the primary part of the Fellowship Examination:—

W. I. Adams; R. A. Austin; T. W. Conway, L.R.C.P. & S.I.; W. A. Fernando, M.R.C.P. Lond., M.R.C.S. Eng.; J. G. J. Green; W. McCready, M.B., B.Ch., Royal University; F. P. B. M'Tavish; M. Shipsey; and R. P. Weldon.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Ernst Grawitz, extraordinary professor of medicine in the University of Berlin and director of the medical department of the Charlottenburg Hospital. He was a younger brother of Professor Paul Grawitz of Greifswald and was 51 years of age. His principal publications referred to his long-continued researches on the condition of the blood in chronic lead poisoning and in many other diseases.—Dr. H. Senator, extraordinary professor of medicine in the University of Berlin.

CENTRAL MIDWIVES BOARD.—A special meeting of the Central Midwives Board was held on July 27th at Caxton House, Westminster, Sir Francis H. Champneys being in the chair. The Board considered the following charges, amongst others, against the midwives whose names are given below and ordered them to be struck off the roll. Amelia Ashton, that being in attendance as a midwife at a confinement she was guilty of negligence and misconduct in that she did not wear a dress of washable material, as required by Rule E. 1; she did not take with her the appliances and antiseptics required by Rule E. 2; she did not adopt the antiseptic precautions required by Rules E. 3 and 7; and she washed the patient in the same water and with the same flannel which she had previously used for washing the baby. Elizabeth Bell, that being in attendance as a midwife at a confinement, the patient suffering from abdominal swelling and tenderness on March 27th, she did not until 10 P.M. on March 28th explain that the case was one in which the attendance of a registered medical practitioner was required, nor did she hand to the husband or the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her, in order that this might be immediately forwarded to the medical practitioner, as required by Rule E. 19 (4) of the rules then in force. Harriet Blowers, that when attending her patients she did not wear a dress of washable material as required by Rule E. 1; that she persistently neglected to provide herself with the appliances and antiseptics required by Rule E. 2; and that she did not take the temperature of her patient, being unable to use a clinical thermometer. Mary Denham, that having been enrolled in virtue of having been in *bonâ fide* practice as a midwife for a year before the passing of the Midwives Act, 1902, and never having passed the examination of the Central Midwives Board, or any other examination in midwifery, she had nevertheless falsely, and in breach of Rule E. 26 of the rules in force before July 1st, 1911, represented herself on her door-plate, and by means of cards and advertisements, as (*a*) "Certificated Midwife by Examination of the Central Board"; (*b*) "Certificated by Examination Central Midwife Board"; and (*c*) "Certificated Midwife by Examination of Central Board." Ann Fox, that being in attendance as a midwife at a confinement, the mother being ill and suffering from retention of urine, she did not explain that the case was one in which the attendance of a registered medical practitioner was required, nor did she hand to the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her, in order that this might be immediately forwarded to the medical practitioner, as required by Rule E. 18 of the rules then in force. Harriet Growcott, that she was uncleanly in her person, clothing, and appliances; that she did not take the temperature of her patients, being unable to use a clinical thermometer; and that she did not keep her register of cases as required by Rule E. 22 of the rules in force before July 1st, 1911. Caroline Amelia Hutt, that being in attendance as a midwife at a confinement, the child suffering from inflammation of the eyes, she did not explain that the case was one in which the attendance of a registered medical practitioner was required, nor did she hand to the husband or the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her, in order that this might be immediately forwarded to the medical practitioner, as required by Rule E. 19 (5) of the rules then in force. Mary Ann Margaret Hyde, that she had on several occasions employed an uncertified person as her substitute, contrary to the provisions of Section 1 (4) of the Midwives Act, 1902. Sarah Jane Leach, that being in attendance as a midwife at a confinement, she failed to adopt the antiseptic precautions required by Rules E. 3 and 7; and that she failed to give proper attention to the comfort and cleanliness of the child during the puerperium, as required by Rule E. 11. Mary Ann Pickering, that at the Birmingham Assizes on March 21st, 1911, she was convicted of counselling and procuring one Louisa Hillier to attempt to procure abortion, and was thereupon sentenced to 18 months' imprisonment with hard labour. Hannah Rhodes, that she cut the patient's perineum with a pair of household scissors without disinfection; she removed the afterbirth by pulling on the cord until it broke and then by inserting her hand into the patient's uterus; and she did not take the patient's temperature at any time. Ann Sant, that being in attendance as a midwife at a confinement, she

did not attend to the comfort of the patient, nor did she remove soiled and blood-stained linen from her neighbourhood, as required by Rule E. 10. Sarah Stanley, that being in attendance as a midwife at a confinement, the patient being ill on March 30th, suffering from headache and severe abdominal pain, she did not explain that the case was one in which the attendance of a registered medical practitioner was required, nor did she hand to the husband or the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her, in order that this might be immediately forwarded to the medical practitioner, as required by Rule E. 19 (4) of the rules then in force. A registered medical practitioner having been sent for on March 31st, she failed to notify the fact to the local supervising authority as required by Rule E. 20 of the rules then in force. Ellen Upton, that she was uncleanly in her person, clothing, and house; that when attending a patient she did not wear a dress of washable material as required by Rule E. 1; and that she did not possess the appliances or antiseptics required by Rule E. 2. The following midwives were censured after charges against them had been considered: Elizabeth Jones and Annie Walker.

BELFAST HOSPITAL FOR DISEASES OF THE SKIN.—At the annual meeting of this charity, held on July 29th, it was reported that during the past year 915 patients had been treated, and that there was to the credit of the hospital a balance of £233 12*s.* 3*d.* The buildings and the equipment of the hospital are in a thoroughly satisfactory condition, and the latest methods of treatment are in use.

Dr. A. Philip Mitchell, clinical assistant at the Royal Infirmary, Edinburgh, has been awarded a research scholarship (value £150) by the Council of the British Medical Association.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The National Insurance Bill.

On Monday, July 31st, the House of Commons resumed discussion of the National Insurance Bill in committee. An interesting debate on the position of hospitals under the Bill arose in the discussion on Clause 12. This clause lays down the manner in which contributors who are inmates of hospitals and similar institutions are to be dealt with. The first subsection runs as follows:—"No payment shall be made in respect of sickness, disablement, or maternity benefit to any insured person during any period that he is an inmate of any workhouse, hospital, asylum, or infirmary supported by any public authority, or out of any public funds, or by a charity, or sanatorium, or similar institutions established under this part of the Bill."

Mr. POLLOCK was able to raise the general question of the relation of hospitals to the Bill by an amendment proposing to leave out the words "or by a charity." The main considerations on the subject were set forth in speeches delivered by Mr. AUSTEN CHAMBERLAIN and Mr. LLOYD GEORGE.

Mr. AUSTEN CHAMBERLAIN said that at a previous stage the Chancellor of the Exchequer had stated that in approaching this question honourable Members ought not to be discouraged by the experience of Germany in regard to hospitals under a system of National Insurance. He was under the impression that the great proportion of German hospitals were State-aided institutions only dependent on private subscriptions and donations. He did not think that the example of Germany gave this country any guidance as to what would happen here. Our voluntary hospital system was old-established, of slow growth, and largely encouraged in recent years by Saturday and Sunday collections. It must be clear to everyone that institutions which had largely been dependent on voluntary subscriptions of employers and workmen could hardly expect equal sums in future when the State stepped in and taxed workmen and employers to provide that which the workmen had previously had to provide for themselves. Where the collections had been largest honourable Members might expect that the hospitals would lose most. He had received information from a meeting which represented 44 hospitals in the midland counties and they calculated that 50 per cent. of their entire income was liable to be adversely affected by the Bill, and in the case of individual hospitals the proportion rose to 75, 80, or even 90 per cent. In these circumstances it was not surprising that hospital managers viewed the provisions of this Bill with something like dismay. He wanted to remind the committee that there was another function fulfilled by these institutions, and that was the training of the whole medical profession of the country. The members of that profession were dependent upon the experience which they got in the hospitals for the progress of medical and surgical science. If anything went wrong with the hospitals the whole community would be losers. He would propose that where the insured person became an inmate of these institutions supported by voluntary contributions or partly by voluntary contributions—if he had no dependents—all the money which was due to him as sick pay should go towards his maintenance in the hospital. If he had dependents the money should be divided between the hospital and the dependent. The Chancellor of the Exchequer had reserved a large sum for treatment in sanatorium for persons suffering from tuberculosis. He suggested that the right honourable gentleman should allot some of that money to hospitals where efficiency had been proved to some central authority. If that were not possible, then for each man sent for hospital treatment there should be some payment from the National Fund. The right honourable gentleman had spoken as if the hospitals would be relieved of much of their work, but many hospital authorities did not share that view and thought that under the Bill they would have not fewer but more people sent to the hospitals. He saw that the Chancellor of the Exchequer had an amendment to provide for the payment under certain circumstances to hospitals from the sickness benefit of persons with no dependents, but it was wholly inadequate.

Mr. LLOYD GEORGE, in the course of his reply, said that it was quite obvious that no system which had for its object the promotion of national health ought to do anything which would impair the efficiency of the great hospitals of this country, and he thought he would be able to satisfy the committee that there was no real justification for the fears entertained by many of those engaged in hospital work with regard to the Bill. By the amendments which would be proposed he thought the faintest shadow of fear ought to be removed. He would give reasons to show that the fear had no foundation in fact. The first thing that would happen under the Bill would be that hundreds of thousands of out-patients would be transferred from the charge of the hospitals to the charge of the Fund. Mr. SYDNEY HOLLAND had told him that the London Hospital was not undertaking the work of medical officers of workhouse infirmaries or of parish doctors. On the other hand, it was not undertaking the work of treating those who were well enough off to pay medical men themselves. It was the class in between that was treated, and this was the class that would be dealt with by the Bill. That would relieve the hospitals of a very heavy burden now cast upon them. If these people did prefer to go to the hospital, he did think that the hospitals ought to have a right to impose some charge upon them. His second point was this: the Bill took away the heavy charge for the treatment of tuberculosis. The charge for this at present was out of all proportion to the number of persons treated. The hospitals were not looking at their diminished charges in this respect. He did not see why the workman should contribute less to hospitals in the future than he had done in the past. A man who at present was paying 6*d.* or 8*d.* to his Friendly Society would pay 4*d.* in the future for his benefits. There was no reason why the man who was now paying an extra penny towards his hospital should not pay the same sum, or more, in the future. He did not think that there was much in the contention that the employers' subscriptions would be diminished to an enormous extent. The diminution of employers' contributions had not taken place in consequence of the passing of the Workmen's Compensation Act, and there was no danger that they would not discharge what they regarded as their fair obligation to their workmen in the future. As to new sources of revenue, he did not rule out the suggestion of Mr. A. CHAMBERLAIN that there might be some sort of committee which would dispense a sum of money in such a way that the hospitals should not be left out. Then the approved societies had the power to make subscriptions, and, he thought, that ought to extend also to the Local Health Committees. There was no power for a compulsory levy, but if the hospital funds were going down and their usefulness being threatened, he thought it would be in the interest of the societies to subscribe. It was said that these societies did not subscribe very readily. Perhaps honourable Members should not depend too much on the volume of their subscriptions. He attached greater importance to the amendment as to the payment of sick pay of those who had no dependents to the hospitals. It meant in the case of the vast majority of bachelors that 10*s.* a week would be paid for the first three months. That was a perfectly new source of revenue. He thought those in charge of hospitals were exaggerating the danger. They were overlooking the diminution in charges falling upon them, and at the same time they were overlooking the new sources of revenue. He thought the hospitals would be much better off in the future than in the past, and everything would be gained by exciting a new interest in national health.

Various views were expressed in the course of the subsequent debate. Mr. H. LAWSON considered that the Chancellor of the Exchequer had very greatly underrated the hospital grievance. He thought that the increased care which was to be taken of the health of the people made it certain that the expenses thrown upon hospitals would be increased, and no means were provided by the Bill to meet the increased expense. It should be made obligatory on the Health Committee to pay for work done in hospitals. Mr. J. SAMUEL objected to

deducting money from benefits for the maintenance of hospitals which were supported by the subscriptions of working men. Mr. CASSEL, on the other hand, contemplated some arrangement whereby at least a part of the sick pay went to the hospital. Mr. LANSBURY acknowledged the work done by the voluntary hospitals, but said that public money ought not to be granted to private institutions without an accompanying public control. Mr. LYTTELTON expressed doubts as to whether employers would contribute as much to hospitals as they did now, whilst in his view the demands on them would be increased. He also contemplated an arrangement whereby some part of the sick benefit should be diverted to the hospital. Mr. O'GRADY took the view of the Chancellor of the Exchequer that working-men would not cut off their contributions to hospitals if the funds fell off to a dangerous extent. Mr. HARWOOD was convinced that the Government would have to face the problem of placing the hospitals on a sound national basis. Sir ROBERT FINLAY remarked that it was widely held by those concerned that the Bill as it stood would prejudicially affect the medical and scientific work of hospitals. Sir RUFUS ISAACS, the Attorney-General, said that the words "or by a charity" left it in doubt whether institutions supported by public subscriptions would be included. Accordingly he would propose to add the words "or by voluntary subscriptions."

The amendment of Mr. POLLOCK was then withdrawn, and the words suggested by the Attorney-General were inserted.

An amendment was then proposed by Mr. AUSTEN CHAMBERLAIN to the effect that the sickness benefit of an insured person should "if he be an inmate or patient of a hospital or institution supported by voluntary subscriptions be divided between that hospital or institution and his dependents (if any) in such proportions as the Local Health Committee may determine, and in all other cases shall be." This amendment was criticised by several Members, Dr. ADDISON remarking that money ought not to be taken from dependents for the sake of hospitals. He agreed that hospitals ought to be paid for the services rendered to sick persons, but the payment should not come out of the sick fund. The Attorney-General, whilst not prepared to accept Mr. CHAMBERLAIN'S amendment, suggested that some arrangement might be arrived at on the Chancellor's amendment, which would come on later. The amendment was accordingly withdrawn.

On Tuesday an amendment proposed by Mr. LLOYD GEORGE was accepted by which a part or the whole of the sickness benefit falling to an insured person who was a member of an approved society and the inmate of a hospital might under a special agreement be devoted towards his maintenance in the hospital. Clause 12 was agreed to.

On Clause 13 a most important amendment, placing medical benefit under the administration of Local Health Committees instead of approved societies, was carried. The clause deals with the benefits to be administered by approved societies or the Local Health Committees. The first subsection runs: "Sickness benefit, disablement benefit, and maternity benefit, and subject to the provisions of the next succeeding section, medical benefit shall be administered in the case of insured persons who are members of an approved society, by and through the society, and in other cases by and through the Local Health Committees; sanatorium benefit shall in all cases be administered by and through Local Health Committees."

Dr. ADDISON proposed an amendment to transfer the administration of medical benefits to the Local Health Committees. He spoke for 40 minutes in a pretty well-filled House which gave him a sympathetic hearing. The speech was closely reasoned. In the first place, he pointed out that the effect of the Bill on the practice of medicine and surgery in the whole country would be profound. The ultimate effect of the Bill upon public health and the welfare of the next generation would depend upon the machinery provided in it for administering medical benefits. The honourable Member considered the conditions under which medical benefit would be administered under the auspices of approved societies in a given area. There would be no common growth and development and no definite mode of coöperation between them. Club practice would be perpetuated. Dr. ADDISON explained to the House the deplorable results of this system. The remuneration to the medical man was often so inadequate that it was impossible for him to give to individual patients the detailed attention which was so necessary. It would be a highly dangerous experiment to apply to practically the whole of the population such a system as hitherto had been accompanied by constant striving. There was something in club practice against the ideals of the practice of medical men, and the great majority of them in the country had declared that they could not work on club lines under this Bill. Club practice was against the development of the best treatment or the adoption of preventive measures. Dr. ADDISON then dealt with the undesirability of underpaid professional work. If the medical men were kept under Friendly Society control, and that were extended by the Bill, there was no doubt that there would be a serious depreciation in the standard of the medical profession at the whole success of the Bill depended upon the efficiency of the medical services. Dr. ADDISON, in conclusion, pointed out that medical benefit could be much more efficiently organised and joined into the public health service under the *régime* of Local Health Committees. Through the Local Health Committees it would be possible to get machinery which could be worked in connexion with the prevention of disease.

Many Members supported the amendment. Mr. H. W. FORSTER spoke from the front Opposition bench in favour of it. He stated that the Bill would be unworkable if the coöperation of the medical profession could not be secured. "We want the best medical attendance," said Mr. FORSTER," "we want uniformity of practice and administration. We shall get that to a far greater extent by placing medical benefit under the Local Health Committees than under the provided societies." Mr. GLYN-JONES, who approaches the question largely from the point of view of pharmacists, gave the amendment his support. Sir PHILIP MAGNUS emphasised the unanimity of the medical profession in asking for the amendment. Dr. ESMONDE, who brings a large amount of personal experience to the solution of such problems, gave the amendment warm support. He stated that it was unquestionable that the way in which club patients had had to be treated was not the way in which they should be treated if the Bill was to be a success. He also emphasised the hostility of the medical profession to Friendly Society control. Mr. GIBBS also warmly favoured Dr. ADDISON'S proposal, and remarked on the desirability of making the medical profession more attractive for the best men. A plea upon behalf of the Friendly Societies was entered by Mr. JOHN WARD, who thought that the services rendered by them had not been recognised in the debate. Mr. C. HARMSWORTH also said that scant justice had been done in the debate to the work accomplished by them. He asked that the medical institutes of those societies should be safeguarded. Sir HENRY CRAIK, who speaks for the medical graduates of Glasgow and Aberdeen Universities, gave a whole-hearted support to the amendment. Mr. BARNES, an important member of the Labour party, also argued in favour of it.

Late in the evening the amendment had the warm advocacy of a member of the medical profession on the opposition benches—Dr. A. P. HILLIER. Dr. ADDISON had spoken from the Ministerialist benches and Dr. ESMONDE from the Nationalist. The combination of these three Members, differing in their general political views, emphasised the feelings entertained by the profession towards Friendly Society control. There were some dissenting voices when Dr. HILLIER remarked that there had been no unreasonable hostility of the medical profession to the Bill. The amendment, he said, would be equitable both to medical men and the Friendly Societies. The Local Health Societies would be the strongest bodies to obtain uniformity of practice, and certainly stronger than the approved societies to deal drastically with the subject of malingering.

Mr. LLOYD GEORGE refrained from intimating the attitude of the Government to the amendment until he had heard the representative expression of views from all quarters of the House. In stating that the Government had decided to leave the matter to the free vote of the House unfettered by putting on the party whips for the division, the Chancellor of the Exchequer said that the amendment affected neither the finance nor the fabric of the Bill. Personally, he had always felt that it would be far better that the arrangements for medical benefit should be in the hands of the Local Health Committees. This proposal, however, could not be carried unless there was a practical unanimity on both sides of the House. The debate showed that there was an overwhelming body of opinion in favour of making the change suggested by Dr. ADDISON. The right honourable gentleman went on to discuss the work done by the Friendly Societies, which in the past had provided medical benefit for the working classes who were not prepared to resort to the parish. He had no doubt that there were cases where the payments to medical men had been very inadequate. However, the medical profession was to some extent to blame in the way in which Friendly Society appointments had been competed for. However, he appealed to those who represented the societies to recognise that the conditions had changed. The expense of medical attendance was going up in the future, as there was to be a higher standard. Drugs also were going to cost more. For these reasons the Friendly Societies should recognise the changed conditions and transfer their benefits to the Local Health Committees at the outset. The Chancellor of the Exchequer pointed out, in conclusion, that the amendment would require some adjustment as to the payments to be made by the approved societies to the Local Health Committees. His own preference was for a mutual arrangement subject to an appeal in cases of disagreement to an impartial body—say the Insurance Commissioners.

The amendment was finally carried by 387 votes to 15, the announcement of the figures being received with loud cheers.

Clause 13 as amended was agreed to.

The Administration of Medical Benefits.

On Wednesday the House of Commons took up consideration of Clause 14 of the National Insurance Bill, which deals with the administration of medical benefit. Several very important amendments were made in its terms. Sir PHILIP MAGNUS moved an amendment confining the medical benefit to insured persons whose income from all sources did not exceed £104 a year. He and other speakers pointed out that this income limit was demanded by a unanimous medical profession. Mr. LLOYD GEORGE took a hostile attitude to the amendment, declaring that a two-pounds a week income-limit

was artificial and would operate with quite different incidence in town and country. He expressed his preference for Dr. ADDISON'S plan to leave the fixing of the income-limit to the Local Health Committees, and to accumulate the medical benefits of persons with superior incomes as a fund which in the first resort would be liable to meet fees due by them for medical attendance. Sir PHILIP MAGNUS'S amendment was negatived without a division. An amendment by the Chancellor of the Exchequer to secure freedom of choice of medical men to insured persons was accepted. Dr. ADDISON'S proposal was then carried by 279 votes to 41. An amendment submitted by Mr. CECIL HARMSWORTH to safeguard the existing medical institutes of Friendly Societies was also added to the subsection. A proposal made by Mr. GLYN JONES to have a free choice of chemists and druggists was also accepted. It will be seen therefore, that the clause has been profoundly altered and extended.

A comparison of the text of the first subsection of Clause 14 in its unamended form with the text of the subsection after it emerged from the discussion in committee will reveal the extent of the changes made.

The subsection as unamended ran: "Every approved society and Local Health Committee shall for the purpose of administering medical benefit make arrangements with duly qualified medical practitioners for insured persons to receive attendance and treatment to the satisfaction of the Insurance Commissioners from such practitioners."

The subsection in the form which it now takes after the incorporation of the various amendments is as follows:—

Every Local Health Committee shall for the purpose of administering medical benefit make arrangements with duly qualified medical practitioners in accordance with regulations made by the Insurance Commissioners.

The regulations made by the Insurance Commissioners shall provide for the arrangements made being subject to the approval of the Insurance Commissioners and being such as to secure that insured persons shall, save as hereinafter provided, receive adequate medical attendance and treatment from the medical practitioners with whom arrangements are so made, and shall require the adoption by every Local Health Committee of such system as will secure:—

(a) The preparation and publication of lists of medical practitioners who have agreed to attend and treat insured persons whose medical benefit is administered by the committee within the area to which the list relates;

(b) A right on the part of any duly qualified medical practitioner who is desirous of being included in any such list as aforesaid of being so included, but where the Insurance Commissioners, after such inquiry as may be prescribed, are satisfied that his inclusion or continuance in the list would be prejudicial to the efficiency of the medical service of the insured they may remove his name from the list;

(c) A right on the part of any insured person of selecting at such period as may be prescribed from the appropriate list the practitioner by whom he wishes to be attended and treated, and, subject to the consent of the practitioner so selected, of being attended and treated by him;

(d) The distribution amongst and, so far as practicable, under arrangements made by, the several practitioners whose names are on the lists of the insured persons who after due notice have failed to make any selection, or who have been refused by the practitioner whom they have selected;

Provided that if the Insurance Commissioners are satisfied after inquiry that the practitioners included in any list are not such as to secure an adequate medical service in any area, they may dispense with the necessity of the adoption of such system as aforesaid as respects that area, and authorise the committee to make such other arrangements as the Commissioners may approve. (Mr. LLOYD GEORGE'S amendment.) The regulations made by the Insurance Commissioners shall authorise the Local Health Committee by which medical benefit is administered to require any persons whose income exceeds a limit to be fixed by them, and to allow any other persons, in lieu of receiving medical benefit under such arrangements as aforesaid, to make their own arrangements for receiving medical attendance and treatment (including medicines and appliances), and in such case the Committee shall, subject to the regulations, contribute from the funds out of which medical benefit is payable towards the cost of medical attendance and treatment (including medicines and appliances) for such persons sums not exceeding in the aggregate the amounts which the Committee would otherwise have expended in providing medical benefit for them. (Dr. ADDISON'S amendment.) The regulations may provide that, in the case of persons who are receiving medical attendance and treatment under any system or through any organisation existing at the time of the passing of this Act approved by the Local Health Committee and the Insurance Commissioners, such medical attendance and treatment may be treated as, or as part of, their medical benefit under this part of this Act, and may provide for the Committee contributing towards the expenses thereof the whole or any part of the sums which would be contributed in the case of persons who have made their own arrangements as aforesaid. (Mr. HARMSWORTH'S amendment.)

University of Wales (No. 2) Bill.

The University of Wales (No. 2) Bill has received a second reading in the House of Commons.

Poisons and Pharmacy (Ireland) Bill.

Captain CRAIG has introduced in the House of Commons a Bill "to make certain alterations with reference to the carrying on of the business of pharmaceutical chemists and chemists and druggists in Ireland.' It was read a first time.

HOUSE OF COMMONS.

WEDNESDAY, JULY 26TH.

Milk and Tuberculosis.

Mr. C. BATHURST asked the President of the Local Government Board upon what day he proposed to introduce the Milk and Dairies Bill; and whether any of the provisions of such Bill had been modified in consequence of the recently issued final report of the Royal Commission on Human and Animal Tuberculosis.—Mr. BURNS replied: Due notice will be given of the introduction of the Bill. I am considering what modifications in the Bill may be necessary by reason of the report of the Royal Commission.

Mr. BATHURST: May I ask whether, in view of the uncertainty and alarm both amongst the farming community and the consuming public, the right honourable gentleman will take steps to accelerate the introduction of his Bill?—Mr. BURNS: I do not agree as to the proportion of alarm suggested. It is mainly to consider the matters, which I see are mentioned in the next question of the honourable gentleman, that I have not introduced the Bill up to the present moment.

Mr. BATHURST further asked whether the right honourable gentleman was conversant with the experiments which had been recently conducted on human beings in Germany in order to test the extent of the risk resulting from the human consumption of milk obtained from cows infected with tuberculosis of the udder, and with the report published last year by the Imperial Health Office of Germany based upon such experiments; whether, in the light of that report, he was advised by the medical experts of his department that the drinking of, as distinct from the inoculation with, cows' milk containing tubercle bacilli was calculated seriously to endanger human health even in the case of children; and whether, in view of the absence of deleterious effects resulting from most of the feeding experiments conducted by the Royal Commission on Human and Animal Tuberculosis, he would, in order to allay undue alarm upon this subject, cause further scientific investigations to be made before taking drastic measures in respect of the national milk-supply on a possibly false hypothesis.—Mr. BURNS answered: The experiments referred to were merely observations on the medical history of 360 persons (151 children) who were stated to have consumed tuberculous milk. My advisers agree with the finding of the Royal Commission on Tuberculosis to the effect that "measures for securing the prevention of ingestion of living bovine tubercle bacilli with milk would greatly reduce the number of cases of abdominal and cervical gland tuberculosis in children," and there is nothing in the facts contained in the German report referred to in the question which is incompatible with this conclusion. It would be superfluous, in view of the many years' work of the Royal Commission, to cause further scientific investigation to be made on the points which they have definitely settled.

Mr. BATHURST: Is it not universally admitted amongst the medical profession that this disease is due more to a predisposition caused through insufficiency of milk than to the presence of bovine germs in the milk itself?—Mr. BURNS: I am aware that that view is held by some members of the profession who are entitled to respect, but there are others equally entitled to respect who hold the very opposite view.

THURSDAY, JULY 27TH.

Plague in India.

Mr. MORRELL asked the Under Secretary of State for India whether his attention had been called to the statement that in the first week of July there were 1848 deaths from plague in India; whether this rate of mortality was unusually high for the time of year; and whether the Government was taking exceptional measures for dealing with the outbreak.—Mr. MONTAGU replied: Having regard to the fact that plague, unhappily, has been very prevalent this year, the mortality reported for the first week in July cannot be regarded as exceptionally high from a seasonal point of view. It marks a great decrease on the June figures and is much below the mortality in the corresponding week of 1907, a year in which plague was similarly prevalent. As I informed the House yesterday, the local governments are fully alive to the responsibilities resting upon them in the matter and are endeavouring to arrest the disease by the use of all means within their power.

Experiments on Living Animals.

Mr. G. GREENWOOD asked the Secretary of State for the Home Department whether he was aware that the total number of experiments on living animals, as set forth in the return for the year 1910, had increased from 86,277 in 1909 to 95,731 in 1910, showing an increase of 9454; how many inspectors there now were under the Cruelty to Animals Act, 1876; and whether he could say how many of these 95,731 experiments were actually seen by such inspectors.—Mr. CHURCHILL replied: Yes, sir, but to prevent misapprehension it may be well to point out that of the increase of 9454, 8403 were experiments of the nature of simple inoculations, hypodermic injections, and similar proceedings. There are two inspectors under the Act; 129 experiments were actually seen by them, and a very large number of animals under observation after experiment were examined.

Mr. GREENWOOD further asked the right honourable gentleman whether the statement that the irregularities mentioned in the Return of Experiments on Living Animals during the year 1910 were the only irregularities that had occurred during that year was based on unchecked information supplied by licensed vivisectors themselves; or whether any, and if so what, means were taken to check such information and to detect and report any irregularities which might not be reported voluntarily by the persons guilty of them.—Mr. CHURCHILL answered: The statement that only two irregularities occurred in 1910 was intended to mean that those were the only ones which are known

to have occurred. The statement is founded not only on the returns and other information which licensees are required to furnish, but also on numerous inspections, on examination of laboratory books by the inspectors, and on information given to them by the heads of laboratories and others.

Mr. GREENWOOD: Is it the case, then, that these irregularities were discovered by inspection of 129 experiments out of a total of 95,000?—Mr. CHURCHILL: Inspections of this kind are by sample.

National Insurance Topics.

Lord CHARLES BERESFORD asked the Chancellor of the Exchequer whether it was intended under the National Insurance Bill to allow Friendly Societies to open dispensaries, and whether all dispensing would be done by qualified pharmacists.—Mr. HOBHOUSE (on behalf of Mr. LLOYD GEORGE) said in reply: It is desirable to secure the best system for the supply of medicines. Consequently no one method of supply should be expressly excluded. All dispensing will be done by qualified persons.

Sir WALTER MENZIES asked the right honourable gentleman whether he proposed to make any provision in the National Insurance Bill, or the regulations to be made thereunder, which would enable insured persons who conscientiously objected to ordinary or orthodox medical treatment to obtain such other form of medical treatment as they might desire.—Mr. HOBHOUSE wrote in reply: Under the amendments put on the paper by my right honourable friend any person will be able to obtain medical treatment from any duly qualified medical man, however unorthodox his methods.

MONDAY, JULY 31ST.

The Nutritive Value of Flour.

Mr. C. BATHURST asked the President of the Local Government Board when his department proposed to publish the long-promised report upon the nutritive value of flour, as at present manufactured, and other foods.—Mr. BURNS said in reply: The report is now in an advanced stage of preparation and I hope it may be issued very shortly.

Death-rate of Nyasaland Natives in the Transvaal.

Mr. FELL asked the Secretary of State for the Colonies whether his attention had been called to the death-rate among the natives employed in the Transvaal mines in place of the repatriated Chinese and to the death-rate among such of the natives as had been recruited from British Nyassaland, Nyassa, and Zambesia; and whether he proposed to take any steps to prevent such recruiting from colonies under the Colonial Office.—Mr. L. HARCOURT answered: The mortality rate amongst the Nyassaland natives in the Transvaal is causing me great concern, and I am in active communication with the Union Government, who hope, however, to see a material improvement in the course of a few months owing to the restriction of tropical natives to mines where proper change houses exist. Further measures may be required, but if they fail the stoppage of emigration may be necessary.

Friendly Societies and Medical Practitioners.

Lord CHARLES BERESFORD asked the Chancellor of the Exchequer, with reference to Clause 14 of the National Insurance Bill, whether Friendly Societies were to have control of the medical practitioners.—Mr. LLOYD GEORGE replied: The answer is in the negative.

TUESDAY, AUGUST 1ST.

Tuberculosis and Butter.

Captain FABER asked the President of the Local Government Board whether the bacilli of tubercle had been found in butter.—Mr. BURNS replied: Tubercle bacilli are occasionally to be found in butter, when they had been present in the milk from which the butter was made. The risk to health from such butter may be regarded as relatively slight.

A Claim to Cure Consumption.

Mr. C. BATHURST asked the President of the Local Government Board whether Dr. Kaye, the medical officer of the West Riding County Council, had, at his request, investigated the claim made by Mr. A. Bryant, of Thornton, Bradford, that he had cured and was curing consumption in an advanced stage of the disease by means of gases which were given out by the maggots infesting putrifying meat; and, if so, with what result.—Mr. BURNS said in reply: I have not made any such request to Dr. Kaye.

"Botanic System of Medicine" and National Insurance.

Mr. JAMES PARKER asked the Chancellor of the Exchequer whether a person who was practising "the botanic system of medicine" would be entitled to render medical aid under the National Insurance Bill.—Mr. ILLINGWORTH (on behalf of Mr. LLOYD GEORGE), in reply, said: Such a person would not be a duly qualified medical practitioner unless he has passed the examination required by the Medical Acts and been registered under those Acts.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

GIBRALTAR.

Sir F. Evans, K.C.M.G., C.V.O., Colonial Secretary of Gibraltar, reporting on the Blue book for 1910, gives the present estimated population as 23,310, that being, of course, the total of both civil and military elements. We have already, and recently, reviewed Major Fowler's excellent report on the sanitary administration of Gibraltar (see THE LANCET, July 8th, p. 117). Although the death-rate was 18·0 per 1000, as compared with 15·09 in 1909, the general sanitary condition was satisfactory throughout the year. The rainfall was 24·01 in., or about 9 in. below the average (33·33 in.) of the last 115 years, whereas in 1909 it was 55·00 in., or 22 above the average. The greatest rainfall in 24 hours in 1910 was 4·53 in. on Dec. 4th. The total number of patients treated in the Colonial Hospital was 673, including 43 remaining in the hospital at the end of 1909. The daily average number under treatment was 45 and the number remaining at the end of the year 1910 was 63. There were 34 deaths. The surgical operations numbered 179, with 7 deaths. The out-patients totalled 10,615. There were 15 patients in the small-pox branch of the hospital and 4 died. In the course of his general observations Sir F. Evans remarks: "Better means of communication with the adjoining country are required. There is an excellent steamboat service between Gibraltar and Algeciras across the bay, but to get to the country beyond the town of La Linea, which is separated from Gibraltar by less than a mile of fairly good road, running across the neutral ground, there is only the sea-shore available. What is much wanted is a well-kept carriage road to join La Linea up with the village of Campamento. If this were provided—and I have reason to believe that surveys are being made with a view to the construction of a road—it would assuredly lead to the opening up of the neighbouring country, and prove of considerable advantage to the residents of Gibraltar, while indirectly adding to the prosperity of the town." The country round the bay of Gibraltar is beautiful, the climate is excellent, and there is no reason to doubt that if proper means of communication were provided many villa residences would soon be built, many persons regarding the situation as rivalling that of any town in the Riviera, both as regards climate and surroundings. The number of persons who pay brief visits to Gibraltar has largely increased of late years. Many stay only a few hours, but others make the place their headquarters from which to visit Spain and Morocco.

A WARNING.

To the Editor of THE LANCET.

SIR,—I should like to warn the profession in London against a man who took some silver articles from my waiting-room a few days ago. He is about 30, well dressed, and speaks with a foreign accent. He presented a card with a foreign name, was clean shaven, and wore "fairy" pince-nez, and carried a book and a parcel, but seems to have called elsewhere the same day under a different name, carrying nothing and (?) wearing a moustache, but no glasses. He showed knowledge not given by the doorplate, and named a friend, who does not know him. Two people here could identify him. The telephone number is 1773 Mayfair, and I should be glad to trace him.

I am, Sir, yours faithfully,

FRANCES EDE.

13, Upper Berkeley-street, Portman-square, W., July 31st, 1911.

MEDICAL CERTIFICATES FOR COUNCIL WORKMEN.

THE Westminster City Council has for some time past had under consideration in committee the question of making a new Standing Order as to the certification of illness of workmen. The Highways Committee recently forwarded to the General Purposes Committee a suggested Standing Order providing, *inter alia*, that in any case in which the committee might deem it expedient sick pay should be subject to the production, at the cost of the council, of a certificate from a medical practitioner appointed by the council that the workman or servant was unable to perform his duties. After perusing the return of workmen's absences during the month of April, 1911, and discussing the matter of the medical certificates received since the operation of the new Standing Order, the Highways Committee recommended that in the case of any man absent from work by reason of illness the assistant city engineer should be authorised to obtain a report from Dr. Norton should he deem it desirable, and the committee suggested that Standing Order LXXXI. should be thus amended. The proposal made by the Highways Committee is one which, if adopted, should in the opinion of the General Purposes Committee, be made applicable to all departments of the council, but before recommending its permanent adoption the committee thought it should be tried temporarily, and the council, on that committee's recommendation, has agreed that the suggestion should be tried as an experiment in the Highways Department until Dec. 31st next, the assistant city engineer to submit at the end of that period a statement giving particulars of the cases dealt with and a report on the result.

THE BATHS OF PÖSTYÉN.

WE have received a brochure which gives an interesting account of this Hungarian health resort and of the methods of treatment adopted there. Pöstyén, the Hungarian name, or Pistyan the German name, is situated in Upper Hungary, 468 feet above the sea, and is picturesquely surrounded by the sloping hills of the lesser Carpathians. It can be reached from Budapest in 3¼ hours, from Vienna in 3 hours, and from Berlin in 13 hours. The natural therapeutic agents are a strong sulphur thermal spring, and a warm mud richly impregnated with sulphur. There are also the numerous appliances providing for radiant light and electric treatment. The mud is decidedly radio-active, a property which it retains even when transported abroad for curative purposes. The cases which benefit at Pöstyén comprise rheumatic affections, sciatica, lumbago, gout, and skin diseases. Samples of both the mud and water may be obtained at the London agency, The Pöstyén Thermal Supply Company, 47, Gerrard-street, London, W. The accommodation at Pöstyén is ample, and special efforts are made to secure the comfort of the visitors, while social attractions are not forgotten. The country around is interesting.

CENTRIFUGES FOR BACTERIOLOGICAL RESEARCH AND GENERAL USE.

AS is well known, bacteriological research is receiving very considerable assistance from the remarkable improvements which of late years have been made in the apparatus employed for the purpose. This is evident from a very complete list of apparatus, which Messrs. Chas. Hearson and Co., Limited, of 235, Regent-street, London, W., have recently issued. Besides Hearson's well-known incubators, and especially the latest ("the anhydric electric incubator"), in which an absolutely constant temperature is maintained by electric current, for the cultivation of micro-organisms, researches in embryology, histology, and so forth, there are now a series of cleverly designed centrifuges which run at speeds up to 25,000 revolutions per minute and yet which are durable and "quiet working." The list is well worth studying not only in regard to the refinements of bacteriological temperatures and methods of separation, but also in regard to other apparatus (chiefly for incubation purposes), the efficiency of which is based on a similar attention paid to exact demands.

THE PINE-YPTA DISINFECTOR.

THIS is a simple device for ensuring the distribution at regular intervals of a certain amount of disinfectant fluid in the flushing cistern. It acts automatically with each flush, the principle of the disinfector being simply that of a syphon. It consists of a neat glazed earthenware pot containing a greasy paste of, amongst other things, pine oil and eucalyptus. There is a lid which screws tight to a rubber band. The lid is hollow and hump-shaped. There is a perforation at the top of the "hump" and a similar perforation below. The "hump" acts as the syphon. As the cistern fills water enters the lower hole of the disinfector filling the hollow "hump." At rest a certain amount of disinfectant is dissolved. When the cistern is emptied it is obvious that as the water-line lowers to the level of the lower hole of the disinfector the contents are discharged into the cistern. The apparatus, which can be obtained from the Pine-Ypta Automatic Disinfector Company, Limited, 22, Tib-street, Market-street, Manchester, works well and automatically after it has once been placed in the right position. Its action suffuses a very agreeable smell, which is acceptable in its way, but between deodorisation and sterilisation there is a gap.

INTERNATIONAL CONGRESS ON TUBERCULOSIS, ROME.

WE are informed by Mr. J. J. Perkins, the honorary secretary of the National Association for the Prevention of Consumption, 20, Hanover square, London, that the Rome authorities have decided to postpone this Congress, which was to have been held in Rome from Sept. 24th to 30th, 1911, until April, 1912. Further particulars will be published. Previous references to this Congress appeared in THE LANCET of March 11th (p. 708) and March 18th (p. 755), 1911.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

THE following Congresses, Conferences, and Exhibitions are announced for 1911:—

April–October.—Rome Exhibition (United Italy's Jubilee).
" 29th–Oct. 26th (Turin).—International Exhibition.
May 3rd–Oct. 31st (Glasgow).—Scottish Exhibition.
" 6th–Oct. 31st (Dresden).—International Hygiene Exhibition (British Section opens June 14th).

May 12th–Oct. 31st (London, Crystal Palace).—Festival of Empire Imperial Exhibition. (Profits to King Edward VII. Hospital Fund.)
" 18th–October 31st (London, Shepherd's Bush).—Coronation Exhibition.
" 19th–Oct. 31st (London).—Earl's Court Exhibition.
June 1st–August 31st (Squirrels Heath, Romford).—Town Planning and Modern House and Cottage Exhibition.
July 31st–August 5th (Dijon).—Congress of the French Association for the Advancement of Sciences.
August 1st–6th (Amiens).—Twenty-first French Congress of Alienists and Neurologists.
" 3rd–5th (London).—British Dental Association, Annual Meeting.
" 12th–18th (Brussels).—First International Congress on Child Study.
" 12th–30th.—E.M.I. (Enseignement Médico-mutuel International) Tour in Scandinavia.
" 15th–21st (Dublin).—Royal Institute of Public Health.
" 21st–23rd (Larvik).—Fourteenth Norwegian Physicians Congress.
" 28th–Sept. 11th (South-East of France).—Eleventh "Voyage d'Etudes Médicales."
" 30th–Sept. 2nd (Berlin).—Third International Laryngo-Rhinological Congress.
" 30th–Sept. 6th (Portsmouth).—British Association.
" 31st and Sept. 1st (Vancouver).—Thirteenth Annual Meeting of the British Columbia Medical Association.
Sept. 4th–9th (Yarmouth).—Sanitary Inspectors' Association. Annual Conference.
" 5th–7th (Philadelphia).—American Electro-therapeutic Association.
" 9th–11th (Ostend).—Fifteenth Flemish Nature and Medical Congress.
" 11th–13th (Vienna).—German Urological Society.
" 11th–15th (Berlin).—Third International Conference on Infantile Mortality (*Goultes de Lait*).
" 11th–16th (The Hague).—Thirteenth International Congress on Alcoholism.
" 12th–15th.—Celebration of the 500th Anniversary of the Foundation of the University of St. Andrews.
" 18th–23rd (Sydney).—Australasian Medical Congress.
" 23rd–Oct. 21st (London, Olympia).—Electrical Exhibition.
" 25th–29th (Karlsruhe).—Eighty-third Meeting of German Physicists and Physicians.
" 26th–28th (Louisville, Ky.).—American Association of Obstetricians and Gynecologists.
" 26th–30th (Brussels).—Third Congress of the International Society of Surgery and Exhibition of Fractures.
" 29th (Edinburgh).—Association of Veterinary Officers of Health. Annual Meeting.
September (Genoa).—International Exhibition of Marine Hygiene.
" (Turin).—Congress of the Association of Italian Railway Physicians.
" (London).—Bakers' and Confectioners' Exhibition.
" (Manchester).—Second Conference of the British Hospitals Association.
September–November (Antwerp).—International Exhibition of Alimentation, Brewing, Wines, and Liqueurs.
Oct. 1st–4th (Liége).—Second Congress of Alimentation.
" 2nd–5th (Turin).—International Congress of Pathology.
" 2nd–6th (London, Royal Horticultural Hall).—Seventh London Medical Exhibition.
" 2nd–7th (Dresden).—Third International Housing Congress.
" 2nd–7th (Paris).—French Congress of Surgery, Twenty-fourth Annual Congress.
" 3rd–6th (London).—Dairy Show.
" 5th–8th (Turin).—Fourth National Congress of Hygiene.
" 9th–12th (Turin).—Twenty-first Congress, Italian Society of Internal Medicine.
" 9th–13th (Cologne).—Seventh International Congress of Criminal Anthropology.
" 22nd and 23rd (Lyons).—Twelfth French Congress of Medicine.
" 25th–27th (New York City).—Annual Conference of Sanitary Officers of the State of New York.
October (Paris).—International Sanitary Conference (to Revise the International Sanitary Convention of 1903).
" (Paris).—First Congress of the International Medical Association for the Prevention of War.
November (London).—Motor Exhibition.
" (Manchester).—Smoke Abatement Exhibition.
Dec. 4th–9th (Havana, Cuba).—American Public Health Association.
December (Moscow).—Third Pan-Russian Therapeutical Congress.

In 1912:—
Jan. 29th–27th (Hong-Kong).—Second Biennial Congress of the Far Eastern Association of Tropical Medicine.
April (Rome).—Seventh International Congress on Tuberculosis.
" (Rome).—Seventh International Congress of Dermatology and Syphilology.
Spring (London).—Second Optical Convention.
May 31st–June 2nd (Berlin).—Sixth International Congress of Obstetrics and Gynæcology.
May (London).—International Horticultural Exhibition.
July (Liverpool).—British Medical Association, Eightieth Annual Meeting.
Sept. 23rd–28th (Washington, D.C.).—Fifteenth International Congress on Hygiene and Demography.
September (Prague).—International Congress of Radiology and Medical Electrology.
(Budapest).—Tuberculosis Exhibition.
(Stockholm).—Olympic Games.

In 1913:—
Aug. 6th–12th.—(London).—Seventeenth International Congress of Medicine.
(London).—Historical Medical Exhibition. (Organised by Mr. Henry S. Wellcome.)
(Chicago).—Congress of the International Association of Refrigeration.

Medical Diary for the ensuing Week.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Low: Malaria.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 12.15 P.M., Lecture:—Dr. Bernstein: Clinical Pathology. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Simson: Diseases of Women.

THURSDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. Dr. Simson: Gynæcological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Morton: Radio-therapeutics and the Use of Solid Carbon Dioxide.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Medical Registrar: Demonstration of Cases in Wards. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (7th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.).

TUESDAY (8th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London, (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.), Royal National Orthopædic (9.30 A.M. and 4 P.M.).

WEDNESDAY (9th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Tottenham

(Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (10th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal National Orthopædic (9 A.M. and 3.30 P.M.), Royal Ear (2 P.M.), Children Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (11th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Royal National Orthopædic (3.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (12th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. I. of 1911, which was completed with the issue of June 24th, were given in THE LANCET of July 1st.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1911 are now ready. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

Agent for the Advertisement Department in France—J. ASTIER, 35, Rue Franklin, Asnières, Paris.

A Lecture
ON
PSYCHONEUROSES.

Delivered at the Medical Graduates' College and Polyclinic on June 12th, 1911.

BY E. D. MACNAMARA, M.D. CANTAB, F.R.C.P. LOND.,
PHYSICIAN TO THE WEST END HOSPITAL FOR NERVOUS DISEASES.

GENTLEMEN,—It is only within a comparatively short term of years that the large class of maladies with which I propose very briefly to deal has engaged the serious attention of the profession. That attention has been attracted not only by the patient labours of many neurologists and psychiatrists, but has been more roughly roused from without by the exploitation of mental therapy by so-called "faith-healers" of many denominations. It is perfectly true that from the remotest dawn of history there is abundant evidence of the existence of diseases which were not susceptible of cure by drugs or other physical agents, but which were cured by some procedure directed towards making an impression upon the mind of the patient. It is further true that except during recent decades such diseases have for the most part been rather contemptuously ignored by the profession, with the not unnatural result that a large field of activity has almost voluntarily been abandoned to the charlatans. But never before has there been the same amount of organised activity on the part of that large body of persons who regard themselves as either innately qualified or divinely inspired to treat disease. Nor are such activities confined to the practice of the unscrupulous upon the ignorant and unwary, but, on the contrary, are widespread among highly educated persons who on a basis of mysticism erect large structures compact of what they call religion and philosophy. It must fall within the experience of many of us to lose our patients to the exponents of such systems, and it is perhaps not too much to say that the remedy lies largely in our own hands.

To affirm of certain groups of symptoms that they are "imaginary" or that they are "merely nervous," and that therefore they must be ignored, or that they can, on the other hand, be cured by a bottle of this or by a course of that or even by surgical intervention, is, from an academic point of view, to put aside the investigation of a large series of most important problems, and from a practical point of view to drive our patients into the arms of those who dogmatise the more vehemently as their ignorance is the more profound, but who at least empirically know that the procedures in which they believe themselves to be adept are at times capable of effecting cures. I believe I am right when I say that there are but few, if any, sects of those who may generically be called faith-healers whose members deny the services of a surgeon in the case of, let us say, a compound fracture of a leg. But a larger number are prepared to deny the services of a physician when the morbid processes are concealed by the superficial structures, and all are prepared to affirm that the services of a surgeon and physician are alike useless and are even nocuous when the symptoms are of a so-called nervous character. The much-abused adjective "nervous" covers many large categories of disease, and in this special connotation generally means the exhibition of the milder mental abnormalities. Such affections are, however, not the only manifestations of psychic disorder, and, in fact, there is no system of the body which may not show symptoms that are directly dependent upon an improper performance of psychic functions. It is from this enormous group that is, for the most part, drawn the class of patients who are benefited by the methods of the faith-healer, whether he be a follower of current cults or an exponent of "higher thought," "newer thought," or "Christian Science." Some study of these phenomena and of the methods which may be used in their treatment will convince one of the profundity of the problems involved, and at the same time of the importance of proper treatment. Merely to enumerate some of the affections will suffice to indicate the wide range covered.

SIGNIFICATION OF TERM "PSYCHONEUROSIS."

It is not altogether easy to define the term "psychoneurosis." A neurosis is an affection of the nervous system in which the anatomical lesion is unknown, and similarly a psychosis is an affection of mentality in which the anatomical lesion is unknown, but such definitions, though convenient, are inaccurate and can only be regarded as conventional and provisional, for to distinguish between an affection of mentality and an affection of the nervous system is often plainly beyond our power, since we can demarcate no boundary where we can say that here mentality ends and here the functions of the nervous system begin. As an example of a disease which we may place in the category of the psychoses I may mention maniacal-depressive insanity, and as an example of a disease which we may place in the category of the neuroses, I may mention those neuralgias which are not accompanied by any structural nervous change. Both the psychoses and the neuroses tend with the advance of pathological knowledge to lose members of their categories to the category of organic disease, but the former nevertheless remain up to the present as a formidably large group. The psychoneuroses are not, as their title might lead one to expect, affections combining the symptomatology of the psychoses with that of the neuroses, but, in fact, form a sub-group of the psychoses in which the clinical phenomena are non-mental, but in which those phenomena have been produced by incidents in the mental life of the patient. The patient, perhaps, does not complain of his "nerves" at all, nor does he always suspect that his nervous system is at fault, but rather he complains of some other system—for example, the gastro-intestinal or circulatory. On the other hand, the patient may ascribe his symptoms to his nervous system, but energetically repudiate the idea that his mind is affected. The outstanding characteristics of these affections are that the symptoms are brought into existence and persist in the absence of any structural alteration in the organ or organs apparently at fault, and that the symptoms date from a period of short or long duration, during which adverse psychic conditions were experienced. To put it quite briefly, the troubles, no matter where they are situated, are of psychic origin. It should be very distinctly understood that these symptoms are neither imaginary nor invented. Symptoms can, no doubt, be invented, and not infrequently are, but persons presenting invented symptoms pass into the categories of malingering or mythomania. Similarly, symptoms can be imagined and not infrequently are, but persons presenting imaginary symptoms pass into the category of hypochondriasis or a form of delusional insanity. In the psychoneuroses symptoms which are neither invented nor imaginary are present, and can often only be distinguished from symptoms of organic origin by taking the etiological factors into account—that is, by a consideration of the psychic stresses to which the patient has been subjected.

SYMPTOMS CONNECTED WITH THE RESPIRATORY SYSTEM.

In the case of the respiratory system we not uncommonly meet with symptoms which appear to be dependent upon psychic causes. For instance, in the case of the larynx, a man, part of whose profession in life lies in the exercise of his vocal cords, may complain of aphonia, partial or complete, arising in the course of his duties. On examination no abnormal physical signs can be found, and the aphonia only occurs at irregular intervals, commences suddenly, and passes away rapidly. If the history of the patient be minutely examined it will in all probability transpire that the affection dates from an attack of what was no doubt laryngitis, and it will probably also become apparent that at the time of the laryngitis the patient was worried by having to give up his work and is still haunted by the fear that he may have to give it up again. A correct diagnosis having been made, it is likely enough that the patient will be dismissed with a prescription and the assurance that he need not be alarmed as to the future of the affection. Frequently such treatment suffices, but not uncommonly the attacks of aphonia persistently recur, the patient seeks further advice, is again and again disappointed with the result of treatment, and finally, impressed by the glamour of some advertisement or moved by the solicitations of friends believing in some particular nostrum, gives himself to the charlatan or the faith-healer and by him is perhaps relieved

of further trouble. A case such as this illustrates the method of origin of a large number of the psychoneuroses. There has been some slight and unimportant organic affection: this was accompanied by worry due to the inability of the patient to carry on his work, and, though of itself of small moment, apprehension of a recurrence has remained and shows itself at times in specimens of what would happen if, in fact, the affection were to return. In the case of a patient whose malady is of the larynx or of the respiratory passages in general, the association of troubles of these regions with the idea of cold being very common, it is quite likely that fussy precautions against the supposed effects of cold will be much in evidence. Among such persons we find those who shelter themselves from cold to such a degree that life becomes one round of searching for and avoiding possible draughts or of varying the number of layers of their clothing with the level of the thermometer; or those who, to the detriment of their digestions, suck cough lozenges all day and all night, or who, to the annoyance of bystanders, alternately clear their throats and blow their noses throughout their waking hours. Some varieties of asthma also appear to be of psychic origin—that is, that the first attack occurred at the time of, or shortly after, an unusual emotional state, and that subsequent attacks have occurred during, or shortly after, subsequent emotional states.

GASTRO-INTESTINAL CASES.

The effect of states of mind upon the functions of the gastro-intestinal tract is well recognised, and knowledge of these effects has in recent years been elevated, chiefly by the work of Pauloff, to a scientific level. Many accustomed to slight degrees of dyspepsia after their ordinary domestic meals are astounded at the digestive capacity of their stomachs after the copious intake of some enjoyable public dinner, while others of habitually good digestive capacity find their dinners spoiled and their digestions temporarily deranged by the honour of having to deliver a post-prandial oration. Among the neurasthenic digestive troubles are so frequent and so marked that etiological theories have been erected ascribing the neurasthenia to the dyspepsia rather than the dyspepsia to the neurasthenia. It is not at all uncommon to hear that certain articles of diet make certain persons sick, and it is difficult, so digestible are some of these articles, to account for the apparent irritability of the stomach. For instance, a patient was for years nauseated by honey, or, perhaps, it would be more correct to say felt nauseated when he saw honey on the table. This dated from some occasion in very early childhood when the patient was sick and spat up a streak of blood after a meal at which he had had honey. The patient was under the impression that he had some special idiosyncrasy which prevented him from digesting honey. After the probable genesis of the idea had been explained to the patient and the improbability of honey disagreeing with so healthy a stomach as his had been insisted upon, he was no longer troubled, and now takes honey from time to time as opportunity affords without the slightest feeling of nausea. Another patient was, in the middle of a dinner party, taken with nausea and had, to his embarrassment, to leave the table. There was no obvious cause for the feeling, but subsequently for some years, although the patient's powers of digestion were good, he was unable to dine out at a mixed dinner party, for to do so invariably eventuated in a feeling of sickness coming on at the table. A third patient, a girl, complained of abnormal sensations chiefly of a "sinking character" occurring from time to time in the epigastrium and which she put down to indigestion. It seemed difficult to ascribe the phenomena to the stomach, but some little time was spent in endeavouring to treat the disorder as though it were of gastric origin. At length, psycho-analysis being employed, the fact was revealed that the time of the first onset of the sensations was coincident with a disappointment in love. The possible origin of the sensations, quite unsuspected either by the girl or by her medical attendant, was explained to the patient and the symptoms rapidly disappeared. These cases of very homely uncomplicated symptoms serve to illustrate psychoneurotic processes affecting the stomach in which the cause seemed plain.

But many cases are by no means so simple, while the symptoms may be of great gravity. Indeed, the clinical picture is often such that it is hard not to believe that serious organic disease is present. Pain in all the forms in which it occurs in dyspepsia of other origin may be complained of, and may be distending or burning, thoracic or abdominal, coming on immediately after food or being delayed for some hours. Stasis and dilatation may actually occur and be in part dependent upon atonicity of the gastric muscles, a condition presumed in these muscles as part of the general atonicity inferred in its turn from the atonic condition of muscles more readily observed. Parenthetically, it may be noted that the atonia of the muscles is seldom if ever of the degree of such atonia as we meet with in tabes dorsalis, and, indeed, is often assumed rather from the statements of the patient than observed from the condition of his muscles. Stasis may also be due to alteration of the character of the gastric juice, and we have every reason to suppose that the latter varies considerably with mental states. The gusto with which a healthy and happy individual sets himself to his meals promotes the proper amount of flow of the proper sort of juice. On the other hand, we find the individual who has been the subject of some depressing emotion firstly losing appetite, then exhibiting those dyspeptic symptoms which follow upon alteration—qualitative or quantitative, or both—of the gastric juice, and later still showing signs of malnutrition consequent upon insufficient feeding. Consider the not infrequent circumstances in which dyspepsia is brought about in the case of the individual who lives by himself. There is nothing probably in his daily work to promote appetite, for it is likely enough carried on mechanically in depressing surroundings and in a foul atmosphere. To each meal such a person sits himself without appetite. His solitary repasts are not lively entertainments, and he regards them as functions to be as rapidly hurried over as possible. He discourages rather than encourages any desire for food that may be present and gradually reduces the time he takes over his meals. Under these conditions an absence of proper psychic stimulus vitiates the secretions, dyspepsia occurs, and the patient further reduces the quantity of food he takes to avoid the discomfort or pain which follows upon taking it. A vicious circle is now entered upon and the patient may eventually present all the symptoms of serious organic disease.

CARDIO-VASCULAR SYMPTOMS.

The heart is even more generally recognised to be affected by psychic states than is the stomach, and since the dawn of history has been regarded as bound up with the emotions and even as their corporeal site. Tachycardia is an almost invariable accompaniment of the more powerful emotions, though the most powerful of all are, at least in some persons, accompanied by bradycardia. With the tachycardia may be associated palpitation, and there are cases in which rapidity of the heart's action and the abnormal sensations of its presence suggest to the patient that he is the subject of heart disease. It is, of course, unlikely that a single attack of such symptoms occurring at the time of some emotional disturbance would create the idea of cardiac disease, but if the symptoms recur whenever the attention of the patient is called to the cause of the original emotion it is not unlikely that the idea will arise. Here may be mentioned the exceedingly common vascular phenomenon of blushing. Commonly associated at certain ages, and for the most part in the female sex with certain emotions, it may last on beyond the usual age limits, and in so doing is liable to become a serious source of annoyance and may even make of the patient an embittered recluse. Not infrequently the origin of the habit is found to lie in an association between blushing and lying or masturbation, suggested in the first instance to the patient by a school fellow or by a quack advertisement.

DIAGNOSIS.

It would be very easy to multiply instances of the occasionally unfortunate effect of the mind upon the body, for there is not one of the systems of the latter which is exempt from such effects. I have given examples of cases in which the respiratory, the alimentary, and the cardio-vascular systems have been affected, but the urino-genital and the nervous system are by no means less frequently perturbed. The nervous system I have purposely disregarded, since many of its abnormal manifestations are commonly recognisable as of nervous or psychic origin, whereas the connexion between a chronic dyspepsia and a preceding psychic event is much less obvious, and my wish has been to emphasise the fact that many abnormal somatic phenomena,

affecting systems other than the nervous, have a psychic source. The correct diagnosis of the psychoneuroses is naturally of the first importance, for to mistake functional disease for organic disease or *vice versâ* is entirely to vitiate therapeutics. It is therefore necessary carefully to examine the patient in order that the abnormal physical signs of organic disease may be excluded altogether, or that it may be determined that the functional symptoms complained of by the patient are out of proportion to the extent of the organic basis upon which they are founded, for it should always be borne in mind that upon organic disease of small moment in itself may be erected a formidable functional superstructure. To some trifling deformity, let us suppose a deflected nasal septum, a patient's entire attention may become devoted. Repeated medical consultations and the reading of medical books serve to further fix the attention of the patient upon the local condition and spur him to hunt for and to discover symptoms of which hitherto he has been unconscious, while constant treatment so much occupies the patient's time that he has but little leisure for anything else. It is manifest that in such a case though the organic basis of the affection cannot be denied, yet that the psychic influences are such that a comparatively trumpery matter has been exalted to a level at which it dominates life to the exclusion of both business and pleasure. So also it may be that the symptoms complained of may be traced to the existence of some organic disease which has long since passed away, but in which the character of the symptoms became so impressed upon the patient's mind that they continue to have an existence not now based upon structural alteration but upon an established psychic habit.

The examination of the nervous system having been completed and the presence of organic disease having been excluded, so far as such exclusion is possible, the mental life of the patient should be inquired into, and it will be found in a large number of cases that the symptoms commenced at the time of or shortly after the occurrence of a period of emotional stress. Without any history of organic disease it will appear that the abnormal phenomena were first noted during a time of personal, domestic, or business worry, or, with a history of organic disease, that that disease was accompanied by circumstances of a harassing character. Over and over again we find that among women the history commences with the nursing of a near relative during an illness, and among men that the symptoms commenced at a time when the patient's prospects in life and the position of his family were put in jeopardy by loss of employment, or threatened loss of employment, from illness or some other cause. At times it happens that the most careful inquiry fails to elicit anything of a psychic nature which can be regarded as a possible cause of the illness, and it is in these cases that the more subtle methods of psycho-analysis may be put in practice.

PSYCHO-ANALYSIS.

Psycho-analysis is the modern term applied to the systematic exploration of a mental field. In part it consists in the methods ordinarily used when we desire to know the content of a person's mind—that is, observation of his conduct in various circumstances, questioning and cross-questioning, and in most cases, if we can rely on the *bona fides* of the person examined, such methods are sufficient. There are, however, cases in which, though the patient believes that he has wholly and with candour unbosomed himself, yet the all-important circumstances of the past have been submerged in his mind by the current of later events and have passed out of the present field of his consciousness, but though submerged in this way the impress of these circumstances has not ceased to act upon the current above, and occasionally obtrudes itself in the shape of phenomena of which the patient complains.

We are very much accustomed nowadays to hear of, and to read of, the "subconscious," and it would appear that the less we know what we mean by the term the more we are apt to talk about it—at any rate, it provides a *locus standi* on which charlatans of all kinds purport to freely move and where, no doubt, they find their living. That which we may premise about such a mental level, whether we choose to give it such a name and to relate it to the conscious or not, is that it appears to be the region of the automatic psychic reflexes. Just as the limbs become educated to perform certain movements, so does consciousness as to the detail of the movements fade away, and it is similarly the case where psychic performances are concerned. We commit a piece of poetry to memory, and while so doing we have at first more or less difficulty in repeating the words correctly, but later on with no effort at all the words come to our lips when the idea which they represent or with which they have associations is roused. At times we are astonished that the words should arise in us at all, for so long have we been unconscious of them, while in other cases the words are only heard when he who utters them is delirious or in some other abnormal state. But not only is it the case that things committed with effort to the memory may subsequently arise in consciousness without effort, but it is further true that past events which there has been no effort to remember, and perhaps, indeed, about which there has been an effort to forget, may crop up either as recollections which are recognised as such or as phenomena which are not connected in any obvious way with the occurrences of long ago. A woman, for example, in early adult life is subjected to the stress of a love affair accompanied by circumstances which her education has taught her to regard as discreditable, and in which social convention demands that she should hide the expression of her emotions. The stress over, she endeavours deliberately to erase the writing on that page of her memory which recorded it, and to a large extent she succeeds, but, nevertheless, the suppressed emotion, having missed the usual channels by which it ordinarily becomes declared, ferments, to use a very crude metaphor, and sooner or later shows itself in the phenomena we associate with psychasthenia, neurasthenia, and hysteria. It is in the endeavour to trace the connexion between the symptoms of these and kindred affections and some preceding event in the patient's life that the subtler methods of psycho-analysis, such as the study of time-reactions, the examination of the trend of the patient's conversation when he is permitting it to run its course without voluntarily controlling it, examination under hypnosis and a critical analysis of dreams, have been developed under the stimulating influence of Freud and his fellow workers.

But the pursuit of the mental trail is not merely of academic interest, for it is hoped, when the lair of the suppressed emotion is at length reached, when the causal connexion between it and the symptoms has been traced, when an explanation of the connexion has been made, and when possibly an expression of the emotion has been given vent to by the patient, that relief may be afforded. The method is not unlike the time-honoured one of the confession of sin, while self-examination is assisted by eliciting that from the patient which has long since passed from his consciousness. I am not here advancing a personal opinion that it is always desirable to dig where much has been discreetly buried, but it remains nevertheless true that there are cases in which a resurrection of the past is the only method whereby we can hope for relief of present symptoms.

OTHER PSYCHO-THERAPEUTICAL MEASURES.

Fortunately, for psycho-analytic processes often take up much time and require an infinity of patience, many patients can be relieved of the sorts of symptoms of which I have been trying to give a short description by simpler methods. From the earliest times the personal influence of the physician has been recognised as being of great importance, and it is hardly too much to say that that influence is of as much value as are most of the physical agents in his armamentarium. Most ailments in an average man's or woman's life are of the minor order which tend to get well without therapeutic assistance, and in such cases progress to recovery is often accelerated rather by the physician's attitude to his patient than by material therapy directed against the morbific agent. Even in the more serious illnesses, which come sooner or later, the physician may produce an effect upon the course of the disease by encouraging the patient, or, if his prognosis has to be a bad one, by endeavouring to inculcate the virtues of patience and resignation. All of us know that if a patient has pluck he has a better chance than if he caves in at once, and it is our duty to elicit or develop in the patient that frame of mind which will put him in heart to endure his ills. If this be so even in the case of those affections in which the cause is micro-organismal or otherwise organic, so much the more may we expect similar beneficial results when the cause is either wholly or in part psychic.

We are accustomed nowadays to the term "suggestion."

Some use it as a euphemism for hypnosis, since the latter is still held by some to have a sinister connotation. But all that suggestion really means is the presentation of an idea or set of ideas to another for his acceptance. The presentation may be made in various ways and under various circumstances. It may be made, for example, under a deep degree of hypnosis when the patient is artificially though soundly asleep; or it may be made, after the patient has been elaborately prepared by the manœuvres usually practised in preparing the ligher degrees of hypnosis, when the patient is in a drowsy state though not soundly asleep; or it may be made as a direct appeal to the good sense of the patient; or, lastly, over a prolonged period of time by the laborious process of educating the patient out of a set of faulty ideas into a set that is healthy. In any case the first point is to gain the confidence of the patient, and the second, by one or other of the methods just mentioned, to neutralise the ideas which by previous examination we have reason to suppose are the cause of the symptoms.

Just as in the organic somatic affections patients demand from us explanations of their symptoms, are satisfied by explanations which are mostly merely tautological and express themselves as being the better for such paraphrases, so in the psychic affections of the class to which I have been referring interpretation of the symptoms affords relief and not uncommonly eventuates in a cure. At times psychotherapeutic methods alone suffice, but at others certain adjuvants are of importance. One of the most prominent features in the well-known Weir-Mitchell mode of treatment consists in the removal of the patient from his usual surroundings and in his separation from relations and friends. In this there are two objects in view—one that the patient may be as completely rested as possible, and the other that the influence of doctor and nurse may be paramount. The field is, in fact, cleared for psychotherapeutic influences. Other important adjuvants are complete rest and improvement of the general nutrition by feeding the patient up. It is very frequently the case that the patient, harassed by his symptoms, is run down and sleepless, and it is in such cases particularly that rest and feeding are required.

It is not possible for the medical man, restrained by his special education and by the knowledge of the limitations of his science and art, to affect, as does the charlatan, omniscience and to impose on his patients with a show of therapeutic omnipotence. In this respect non-scientific so-called healers must for ever have the start of him, but there is no reason to doubt that he may recover from them much that he has lost if he will recognise to the full the very large influence that the mind has upon the body, both to afflict it and to heal it.

THE PRESENT POSITION OF RADIUM EMANATION-THERAPY IN GERMANY.

BY DR. W. ENGELMANN.

SLOWLY but surely the interest in radium emanation-therapy is growing in Germany. Universities, academies, and larger hospitals are becoming more and more occupied with this new method of treatment, seeking to investigate scientifically its essential nature entirely apart from the Kur administrations, whose attention is naturally concentrated on the practice of this therapy by means of their radio-active waters. Emanation-therapy has undergone frequent changes, short though the period is since its introduction; various apparent objections have explained themselves, and, as the close of this article shows, a mean position has been arrived at, although the precise rules now laid down cannot dispense with an experimental foundation.

Upon the discovery that the greater number of natural mineral waters are radio-active—i.e., contain radium emanations, it followed that their remedial effect must in part, at least, be attributed to these constituents. The lively interest thereby awakened in all health resorts, however, was considerably lessened when it was ascertained that, although all these springs certainly contained such emanations, few possessed them in sufficient quantity to be of therapeutic value.

The discovery that emanation water could be artificially produced—i.e., that ordinary, inactive water could be made radio-active by contact with a radium preparation emitting rays—was a considerable advance in emanation-therapy. Emanation water can now be therapeutically and experimentally applied up to any desired strength. The first reliable clinical observations dealing with radium emanation-therapy and its introduction are due to Dr. Löwenthal of Brunswick. Observations made at springs possessing strong emanatory constituents are of service in proper considerations as to the size of the dose and the quantity serviceable or injurious to the body. Communications from various sources include the observations made on a large scale at Kreuznach and already published. In all places the indications summarised at the close were almost identical, and they still practically remain so.

It has been ascertained that not only are the Kreuznach springs radio-active to a high degree, but that the solid constituents also contain radium—that is to say, that the well "sinter," a sediment that precipitates itself in the brine tanks,[1] is impregnated. It exists here in such quantities that it is worth while to undertake its concentration in order to obtain highly valuable radium combinations.[2] It thus becomes quite clear why a hundred years ago the Bad physicians preferred this sinter for bandages and therapeutical purposes. They extolled its extraordinary power of furthering resorption, in many cases surpassing that of mother-lye—an interesting empirical practice forestalling the proof of science. Apparatus, erected on a large scale, is used for the preparation of emanation water, which is added to the brine (already very strongly radio-active) in the bath pans. Exceedingly valuable radium salt obtained from sinter is used for all kinds of medical preparations, such as salves, compresses, and injections.

Emanation being recognised as an effective agent in the form of a modified gas and possessing the qualities of gases, it was at first maintained that the principal effects obtainable through the bath and drink cures were derived from the gas constantly escaping from the water and conveyed to the body by inhalation—i.e., through the lungs. A step further led to the conclusion that the baths, as such, were superfluous, and that it was more practical to extract the emanation and inhale it in gaseous form. Indeed, some physicians practising emanation-therapy actually made use of the inhalation method in the first instance. Last January Professor His of Berlin reported to the Berlin Medical Association that he had obtained numerous favourable successes with emanation by placing the patients in an "Emanatorium," i.e., in a small compartment containing air laden with the emanation, where they remained for several hours. Theoretically this appeared quite comprehensible, but it needed confirmation. Admittedly, emanations are very quickly eliminated by respiration; it was hoped that by placing the patients in emanation rooms this elimination would be prevented, and that in a short time equalisation between emanation air absorbed by the blood and the laden atmosphere would take place. It is, however, very doubtful whether the solution of the problem is so easy. In addition to being a simple, indifferent gas, emanation has other properties, including the dispensing of induced activity—i.e., the emanation is precipitated on all solids with which it comes into contact, such as bodily tissue, liquids, and cells. Nevertheless, the results of inhalation were good and indisputable, and the question now under discussion is whether all other methods of application, such as bath and drink cures, are to be abandoned in favour of the inhalation cure.

In reference to emanation bath treatment Löwenthal made the statement that emanation could not penetrate through the skin into the organism. In contradiction of this I was able last year, at the Medical Clinic at Bonn University, to prove that emanation can be taken up very well by the body, through the skin, although it can be traced only in small quantities. The baths, therefore, again received their due, since experimental proof of the justification of their application was forthcoming. On the other hand, the effect of the rays issuing from the emanation and its decomposition on the skin, nerves and their terminations, and blood-vessels, ought

[1] To obtain salt and mother-lye brine is passed seven times over the graduators, then collected in tanks in graduator-houses, and afterwards subjected to operations for obtaining salt. The residue, a yellowish-brown fluid, is the celebrated Kreuznach mother-lye, used for strengthening brine baths.

[2] A radium factory has existed in Kreuznach since 1908, being the only place in Germany where radium salt is obtained on a large scale from its own wells.

not to be undervalued. Evidence in support of this was obtained by allowing emanation to operate on various parts of the body in the form of compresses and wrappings. This explains the great success often observed on the application of the emanation. Only recently Professor Strassburger of Bonn recorded in the *Münchener Medizinische Wochenschrift* the great success he has obtained, and strongly recommended the application of baths and poultices.

It has been proved beyond doubt from clinical observations in successful cases that cures or considerable improvement, often beginning with a typical reaction, have been observed after drinking radium emanation water. The objection that a part of the emanation enters the lungs and blood by breathing—i.e., that even here inhalation is the effective method—lacks probability at the outset. I have been able to prove, in the case of a dog that had a fistula in the duodenum, that the entire emanation, which was administered in the form of emanation water through a pharyngeal catheter, entered the bowel without any essential loss—i.e., in the same degree of concentration. Also very little emanation was traceable in the fæces. The whole quantity of emanation was therefore absorbed in the bowels and transferred to the tissues. It is traceable indeed in the respiratory air in such cases, and that at a considerable length of time after having been drunk, and even after having been injected into the bowels, during which time it must circulate in the blood. A depôt has been established, so to speak, in the bowels, whence the emanation enters the blood and a pharmacological effect is obtained. The presence of emanation in the blood of those who have drunk emanation water has been successfully demonstrated.

In conclusion, the following experiments which I recently made in the Berlin Pathological Institute ought to be convincing, and to persuade even the sceptical of the extraordinary influence that emanation exercises on the juices of the tissues when taken per os. I injected uric acid crystals into the subcutaneous tissue of rabbits, producing deposits similar to the tophi of those suffering from gout. I administered emanation water through a pharyngeal catheter and a very rapid reabsorption of those deposits took place under the influence of the emanation. Control animals treated with inactive water did not show this rapid result. I studied the effect after 1, 2, 3, and up to 14 days in paraffin sections of the swollen deposits. The differences were very obvious. The changes, by-the-bye, were of a similar nature to those found in similar trials at Professor His's clinic. The animals here, however, were in emanatoriums, and the effect of a lengthy stay in the emanatoriums was the same as with my animals after taking every day only one dose of emanation water.

There can therefore be no doubt about the effectiveness of the method in which the emanation water is drunk, and as its application is simpler, cheaper, and more convenient it may, in many instances, be preferable. On the other hand it is not to be disputed that where there exists a possibility of using emanatoriums good results will be obtained. In order to avoid the disadvantages connected with the cost, owing to expensive installation and the apparatus being a fixture and thus preventing many from benefiting from the therapy, I have, in conjunction with Professor Bickel of Berlin and Director Neumann of Kreuznach, constructed a simple inhaler possessing the advantages of being cheap and portable; it is capable of being used by those who are bed-ridden, whilst the therapeutic dose is very exact. If one possesses a Kreuznacher Neumann'schen activator which produces an emanation water of sufficient strength, one can by means of it administer the bath, and supply drink and inhalation cures.

There can be no doubt, according to present views in regard to emanation-therapy, that a combination of all three methods may be desirable in the case of an emanation cure. We allow the patient to take his emanation water two or three times daily, then he takes a lengthy emanation bath, and finally he strengthens the effect by remaining in an emanatorium or by the use of an inhaler. This energetic treatment is applied to patients suffering from general assimilatory diseases, especially in cases of gout. When local disorders are in question poultices are preferred, as recommended by Strassburger, whereby an extraordinarily intensive effect may be obtained upon a given spot by emanation.

The indications for emanation-therapy have been strengthened by ample experience. The conditions for which the treatment is indicated include gout, chronic rheumatism, sciatica, neuralgia, neuritis, as well as exudates and growths which need energetic means to promote absorption. It is proved by the study of the biological methods of operation that radium emanation especially exerts a very great influence on ferments, such as pancreas-ferment, pepsin sour-milk fermentation, autolytic ferment, and diastatic ferment. Recently, together with Dr. Wohlgemuth of Berlin, I have succeeded in demonstrating a distinct influence on glycolytic (sugar-destroying) ferment. How far this may be applicable to the group of diseases in connexion with disturbances of sugar secretion we do not attempt to decide, but in any case this result is an interesting addition to the biological effects of this mysterious agent.

Bad Kreuznach.

INSTITUTIONAL HYDROPATHIC TREATMENT AS COMPARED WITH SPA TREATMENT FOR CERTAIN TYPES OF INVALIDS.[1]

BY THOMAS D. LUKE, M.D. R.U.I., F.R.C.S. EDIN.,
MEDICAL SUPERINTENDENT, THE HYDROPATHIC, PEEBLES, N.B.

AROUND the word "hydropathic" there has always existed a certain amount of opprobrium, from its very initiation, more particularly in the eyes of the profession. At the very beginning of hydropathic treatment in this country so much was claimed for "the cold water cure," which had been made famous by the publication of Captain Claridge's book on Grafenberg, that a certain section of the public became so affected with the craze as to carry the whole matter to extremes. This is often the case with new methods of treatment, not only with the public, but, one regrets to say, with the medical profession. The result was that the entire system was laughed at throughout the country and was caricatured in *Punch* and the other illustrated journals of the day. We have seen much the same happen in the more recent "sour milk craze."

Some large establishments were erected, however, in various parts of the country, such as the Ben Rhydding Hydropathic, where Dr. R. McLeod flourished and made a fortune. Dr. W. C. Gully, the late Speaker's father, achieved some success at Malvern, while under the very eccentric direction of its lay founder—John Smedley—the institution still bearing his name commenced its career of almost uninterrupted prosperity. Another more modest establishment was Dr. Rayner's at St. Anne's Hill, near Cork. These establishments were all more or less seriously conducted as places for treatment. During the past 30 or 40 years, however, there has sprung up all over the country a certain class of establishment—really of the unlicensed hotel or boarding-house type—which has done nothing but perpetuate the prejudice against the word "hydro." While the rates for accommodation are distinctly lower than the average provincial hotel, the accommodation offered is not so good, and no claim is made to offer any real therapeutic facilities to visitors unless change of air and a Turkish bath be so considered.

The introduction of amusements of the frivolous sort in and out of season does little but irritate the seeker of health, whose inner man, moreover, is usually not satisfied but disappointed. There are, indeed, very few establishments in this country which in any way resemble the "kur-anstalten" of Germany—general sanatoriums not admitting consumptives such as Dettweiler's establishments, in which, though hydrotherapy is employed it is combined without reserve with all known and tried therapeutic measures; where, in short, the treatment is eclectic, and so long as the patients are cured, anything furthering that end from psychotherapy to quinine is employed.

[1] A paper read at the annual meeting of the Edinburgh Branch of the British Medical Association on June 24th, 1911.

That there is room, and, indeed, a demand, for establishments of this nature in Great Britain, there can be little doubt. Of course, the financial side has to be carefully considered, and we have probably not been sufficiently educated up to this class of treatment to ensure a *large* establishment for purely and simply health purposes being carried on at a profit. For business purposes guests other than invalids have to be admitted and catered for in an establishment of any pretensions, but provided the serious purpose of the institution is for treatment these people will but help to keep the atmosphere healthy and from being unduly oppressed with invalidism! Moreover, invalids often prefer to have some relative with them, so that a general sanatorium of this description can scarcely be run on the strict disciplinary lines of a consumptive cure place. At Smedley's the proportion of invalids under treatment varies from 50 to 70 per cent., the latter being quite high enough a proportion for the preservation of a cheerful atmosphere in an establishment where the patients are not segregated in wards but mix with one another freely.

There has been a great deal of outcry of late as to the excessive and unnecessary extent to which patients are sent abroad to Aix, to Vichy, or to Plombières, rather than to our own Bath, Harrogate, or Cheltenham. It is pleasant to know that to some extent our own watering-places are gaining a foothold, that municipal enterprise and good management, with adequate capital outlay, are leading to increasing prosperity. Some of them are now afforded an ample patronage, and in the season an embarrassing one. Nevertheless, one cannot help feeling that this patriotism and discrimination exercised in advising patients where to take "the cure" might go a step further. There is no question but that a large section of patients remain chronic invalids at home and do not regain their health at a spa simply because the whole circumstances and *ménage* of a spa are entirely unsuited to them. One is compelled to think that too often, when selecting a "cure" place for a patient, medical men do not take into account with sufficient care the respective physical and mental capacities or incapacities of the patients themselves. Of the mental incapacity I had recently a striking instance. An old gentleman came to me with a minor skin ailment of gouty origin, who had been advised to go to Harrogate by a consulting physician. His memory was absolutely non-existent, and even in the comparatively limited confines of the institution to which I am attached he was perpetually losing his way or his hat. Too often there seems rather a rule-of-thumb method of saying, "Harrogate for the gouty and over-eating folk, and Buxton or Bath for the rheumatic."

In deciding which place is likely to benefit any special patient it would seem wise to run over the various factors in "a cure" which do a patient good. Perhaps we would put first of all the change from the normal and usual environment of the patient, and the importance of this can scarcely be overestimated. This being, on all hands, recognised in the taking of an annual holiday, seems to need no amplification. It is invariably found by the laity, whether they invest in vibrators, in high-frequency outfits, or in electric-light baths, or if they take to drinking sulphur waters to satiety, that they do not—nor will they ever—derive the benefit from such combined treatment as they have possibly done previously from similar measures at a spa or hydropathic. For one reason the applications are made without the guidance of a trained physician or special attendants, and the patients get no better results than they would by dosing themselves with drugs—though possibly running the risk of less harm. But quite apart from this they are probably carrying on their usual avocations, and very likely perpetuating bad habits, dietetic or otherwise, which are the very first origin of the indisposition. Moreover, they have none of the distractions and amusements afforded by a watering-place, nor do they meet with the new and often interesting acquaintances, and so be in a position to while away the time and forget physical disabilities. For there can surely be no better anæsthetic or more wholesome restorative for the neurasthenic than exchanging ideas on a subject of really keen mutual interest with another man or woman. I submit that the benefit derived from a visit to a "cure place" or sanatorium is in a large measure due to the proper regulation of the patients' lives as directed by the physician in whose care they have placed themselves, and, one may add, to a willingness on their part to do some things and not to do others in a way which would be quite impossible or irksome to them when at home. Many people ordinarily intolerant of any sort of restraint are rather tickled by the novelty of the thing *for a time*, and there is a certain type of man who takes a pride in the severity of the restriction which is imposed upon him by the new doctor, which he considers to be but in keeping with the size of the fee charged for the advice!

A fashion has got about of late, more especially since radium has been in vogue, to attribute the benefit above referred to to physical rather than psychical influence—viz., to radio-activity in the waters. This, indeed, has the support of no less an authority than Dr. A. P. Luff. Personally I think such ideas should be accepted with the gravest scepticism as really resting on pure conjecture. Dr. Luff says: "If the efficacy of any mineral water depended solely on its watery constituent I do not for one moment think that the resort of sufferers to the various mineral water springs would have so successfully stood the test of centuries as it undoubtedly has. The fact is that in judging the effect of mineral waters we have been under the domination of the analytical chemist, and our deductions have been biassed and cramped. I am satisfied that analysis is unable to convince us of the state of the salts dissolved in the waters. Most of the natural mineral waters have been found distinctly radio-active, and the lower the mineralisation the greater the radio-activity. A natural mineral water at the moment of its discharge from the earth is radio-active, whereas ordinary drinking water is not possessed of this property in any appreciable degree. Hence the desirablity of drinking the water at its source, since in bottling and keeping its radio-activity may in great measure be lost. When we consider the influence of radio-active emanations on new growths and various morbid tissues, is it too remarkable to conceive a radio-active mineral water will exercise a potent effect on those morbid changes within the body which are connected with abnormal tissue metabolism?"

With all respect I must differ from these conclusions. Surely we have more ground for attributing the cures to psychical effects and change of habit than anything like radio-activity? All we know of radium is very imperfect. While more convenient than X rays its efficacy is in many ways no greater, and at the recent Brussels congress it has been much discredited as a therapeutic agent. Looking back on past fashions one does not feel too bold in saying that in a few years' time it will have found its niche in therapy, and possibly be considered to be too dangerous to the patient and operator to use to any extent. Its efficacy is based on the production of a marked local reaction on morbid tissues, especially in new growths. Is it not the wildest imagination to think that an atonic stomach, a passively congested liver, exhausted neurons, or granular kidneys can derive the smallest degree of benefit from this very radio-active power contained in a water? Is it not conceivable, indeed, that such conditions might be hurtfully influenced, and just as probably—if they are influenced at all?

With astonishment we read some months ago in the reports of a speech by the chairman of a mining company very sanguine remarks as to the high degree of radio-activity of the water running into a particular mine—that it was twice or more as radio-active as the Harrogate water: *ergo*, must be more valuable therapeutically. The suggestion was accordingly brought forward that the vicinity of the mine, where pitchblende was being sought and obtained, should be turned into a spa. I have not yet seen a prospectus of such a new concern, but it may still appear, and when such theories are brought forward can we wonder if the enterprising company promoter grasps the opportunity for personal gain?

I have a great respect for some spas, and feel certain that their reputation rests on something less nebulous than *radio-activity*. It rests on the fact that alkalis neutralise acids—a very old bit of chemistry; on the efficacy of sulphur, well known to our grandparents as "a safe family remedy"; on the efficacy of heat, moist and dry, in relieving chronic and acute pain; on the admirable organisation of spas by the bath committee or manager of the various municipalities; and last, but not least, on the number of able scientific physicians who practise in the best-known watering-places in this country and abroad.

Whatever advantages there may be about a spa—and there are many—there can be no disguising the fact that there are

at least two very obvious drawbacks. The first is the risk of the patient catching cold while returning from the pump-room after a Vichy douche or some kind of hot bath. This especially applies to English spas in spring and winter time. At Vichy, as is well known, the greatest care is taken of patients in this respect, and they are carried back to their hotels or rooms well wrapped in blankets. However, in our climate it is different: the patient, from motives of economy, either walks back or goes in a draughty cab. Serious chills have been taken in this way, and when patients suggest coming for treatment by train and returning the same day I strongly advise them against it; for very often the good obtained is much overbalanced by catching a severe chill. Another tangible objection to going out for baths is the added fatigue where the patient is at the start run down and overtired.

All hydropathic treatment—packs, douches, and sweating baths, for some time at any rate, rather "take it out" of the patient, as it is expressed. Add to this the fatigue of changing clothes three or four times a day, including dressing for dinner at the hotel, and quite apart from any walking which the patient is ordered or may take, a heavy day's work is put in. It would seem very ill advised that the Harrogate municipality has passed a by-law prohibiting the use of any medicated bath in a hydropathic within the town boundary, and so compelling patients to go to the Royal Baths for their treatment, and interfering with any private enterprise. The policy seems a very shortsighted one, and the treatment of big ratepayers arbitrary in the extreme.

A walk before breakfast to the pump-room for their sulphur water, and a later visit for more water, for massage, or gymnastics, or liver packs can do nothing but good to an over-fed and over-drinking gourmand and the like. But the case is markedly different with other types of patients. One or two instances will make the point more clear.

In June, 1910, Dr. H. Garnett Wilson, Glasgow, asked me to see a patient with him in Glasgow with a view to her coming to Peebles for treatment if at all fit. She was a maiden lady of some 54 summers, in a very wretched condition, practically living in bed, who had spent her life as an invalid. She was thin to emaciation—white haired, haggard, and hysterical, with a rapid pulse of 90, often running up to 120 or more. She suffered from marked mucous colitis with severe constipation, and had dieted herself down to slops and toast, and very little of that. She had only been outside the house about three times in the preceding year. She was a difficulty to her medical adviser, as well as to her relatives, being querulous and morbid to a high degree. A long journey was out of the question, but about a fortnight after I saw her she came under treatment at Peebles. She arrived more dead than alive and looked so very ill that she was supposed to be dying by the maids. She was one of the most difficult patients I ever had to do with. Beginning treatment very carefully and gradually, increasing massage, with a more liberal diet, which she took at the sword's point practically, she was slowly brought back to a degree of health. In a three months' stay she gained 16 lb., the mucous colitis and the associated pain were subdued, and the patient's general condition was so vastly improved that before she left she was able to take an interest in amusements and to take short walks.

Now, to such a case, a change from the home environment is undoubtedly essential if good is to be obtained, and the discipline of an institution and immediate touch with the medical attendant are almost as essential. The fatigue of treatment, especially the Plombières douche, was very trying to her, and anything like going outside would have made it impossible. To such a patient I submit sanatorium or hydropathic institution treatment makes all the difference between going down the hill and regaining health, and a spa would be out of the question. In a well-conducted sanatorium the physician spends the day in and among the patients, more or less, and sees them in various ways, and hears a great deal about them from nurses and attendants, which throws valuable sidelights on each case, and gives him a knowledge which even a family medical attendant calling day by day might find it difficult to obtain.

Another patient of the same class was sent to me in June, 1909, by Dr. W. A. Stephen, Loftus-in-Cleveland, Yorkshire. Her age was 34 years. For some time she had been in a very anæmic condition and suffering from a certain amount of pyrexia. There was a morning and evening elevation of from half to one degree, but without any notable perspiration. The patient was apathetic to a marked degree and very shy and silent. It was difficult to get very much out of her, and she spent a great deal of time lying about in her room, being unable to take more than a little exercise. The anæmia was pretty intense, the reds counting about 1,800,000, and the hæmoglobin about 40 per cent. The chest was thoroughly overhauled by myself and by the physician of a sanatorium for consumption who happened to be staying with me at the time, and we both considered it clear of any mischief. On careful examination of the mouth I found that the patient had very bad teeth; indeed, they were carious and covered with tartar. The breath also was bad. I strongly urged the removal of the whole of her teeth, with a view to improving her digestion and the elimination of any degree of oral sepsis. This was accordingly done by a dentist, and from that day the patient steadily improved. The temperature ceased to rise both at night and in the morning, and the blood condition changed for the better. The patient was put on a liberal diet, kept in an open-air chalet, and given "Carnine Lefranc." At the end of August, on my advice, she went up to the Speyside district and returned home in September perfectly well, having gained over a stone in weight.

Other cases could be cited, but these two will serve to demonstrate my point. In both instances, only by keeping in very close touch with the patients was it possible to get them out of the "slough of despond" of misery and ill-health into which they had sunk. To patients so gravely ill I submit that a spa—and a spa in the season of all places—is in no way adapted, with residence in rooms or hotel. Hydrotherapy has its disadvantages even when administered under skilled direction. In cases of this nature one never knows how patients will stand any special treatment. This being so, in the first place, special treatment should not be given except with the medical man within call, so that a report can be made to him at once of any untoward effect. For instance, in the case just cited, as the patient improved she was put on to a rain bath and Scotch douches for the anæmia. The effect of the first one was to make her faint and to induce a condition of considerable collapse. I was sent for immediately and got her around, and in spite of the first unpleasant experience she persevered with a little coaxing, with the best results. But, as a rule, patients of this class do not flourish if simply prescribed for and handed over to the tender or other mercies of the bath attendants until they see their medical adviser again. They are, in short, cases for *institutional* treatment rather than for a visit to a spa.

There can be no question but that the poorer classes who become hospital patients have a great advantage in some ways over better-class paying patients. Chaffingly I said to a medical friend recently—a hospital physician—that nowadays the thing seems to be to *keep patients under observation*, rather than treat them in hospitals, more particularly teaching hospitals. Now, it is just this careful observation which is in many cases of the greatest value to the patient, especially the chronically ill person. The house physician and the senior and assistant physicians all examine the case, overhaul the patient, and an accurate diagnosis is made. Every system of the body is investigated, the blood-pressure repeatedly estimated, and blood counts are made.

Thus there would seem to be really a call for institutions of the above type for better-class people in this country—not nursing homes, but general sanatoriums where patients can be observed and investigated in like manner. Such establishments in no way constitute themselves a rival to the family medical adviser, to consultants, or to spa physicians. From the spas they should be differentiated as treating a different type of case. So far as the former are concerned, the physician to such an establishment should be simply a useful colleague, his duty being to treat the patients by methods which for one reason or another have not previously been available, to report progress from time to time to the home practitioner, and to shed any light which can be shed on obscure cases by close personal observation, to the end that the patient may regain his or her health, and that the much-tried medical attendant may be relieved of what often becomes an intolerable plague—an uncured chronically ailing nervous patient.

Peebles.

A CASE OF COMPLETE GASTRECTOMY.

BY B. G. A. MOYNIHAN, M.S. LOND., F.R.C.S. ENG.,
PROFESSOR OF CLINICAL SURGERY, UNIVERSITY OF LEEDS, ETC.

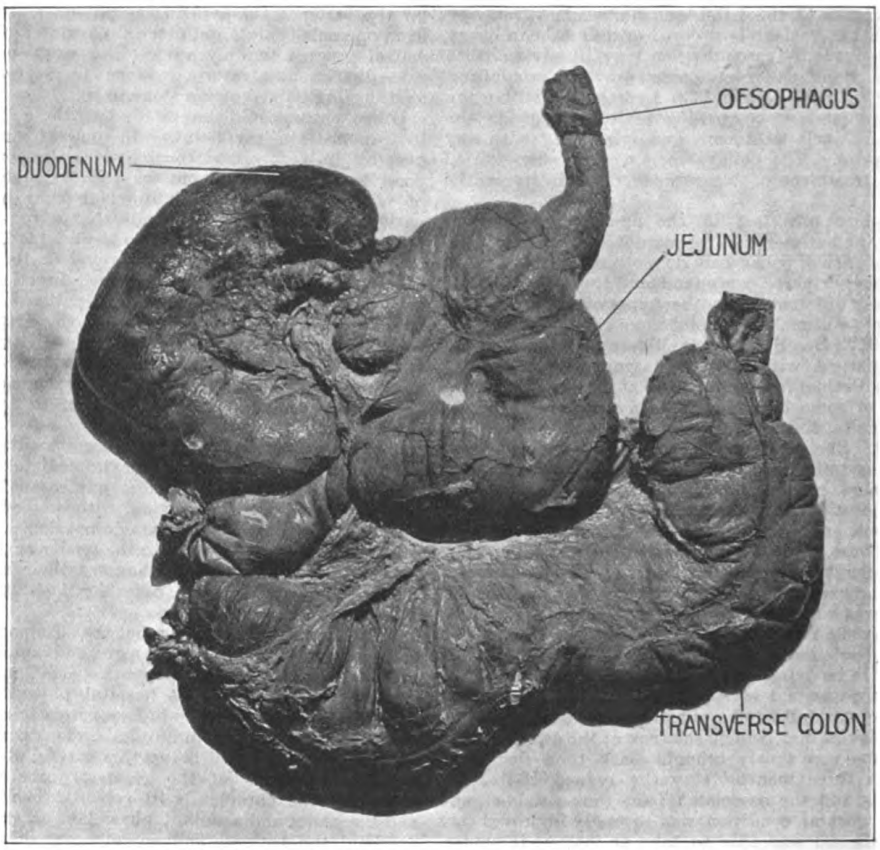
IN THE LANCET of Dec. 21st, 1907, I recorded "A Case of Complete Gastrectomy." The patient was a man, aged 43, who had suffered for two years from gradually increasing distress after food. At the operation a small, greatly thickened stomach was found, and as no healthy part of its wall could be discerned the whole organ was removed. The cut end of the œsophagus was stitched to the side of a loop of jejunum, brought upwards through an opening in the transverse mesocolon. The pathological report of Dr. F. Craven Moore stated that the stomach was involved in "a neoplastic change of a particular type which has its analogue in the so-called atrophic scirrhus met with in the mammary gland."

The patient made a good recovery from the operation. He was shown at a meeting of the Section of Surgery of the Royal Society of Medicine on Dec. 19th, 1907; and in July, 1910, he was seen and examined by the members of the American Society of Clinical Surgery who were then in Leeds. He died on Jan. 31st, 1911. During the three years and eight months that he lived after the operation he was under the constant observation and the occasional care of Dr. Geoffrey Thompson of Scarborough, who has kindly given me very full details of his progress.

The patient was perfectly well up to the early part of the year 1910, when he began to show the evidences of a profound anæmia. He was strikingly pale and breathless, and he lost weight. Under treatment, however, he improved, and in May, 1910, his colour had returned and he was able to ride and drive and attend to matters on the farm. In August, 1910, he began to fail again; he became easily tired, though he still tried to carry out the greater part of his work. His appetite remained good and he had no indigestion. In October the signs of anæmia reappeared, he grew much weaker, and had to cease work. He began again to lose weight, his appetite vanished, and he occasionally vomited. There were no abnormal physical signs of any kind in the chest or abdomen throughout the illness. Soon after Christmas, 1910, he had to take to his bed, and he died on the last day of January, 1911.

I saw the man myself on many occasions. He expressed himself as feeling well and vigorous, and he had gained 2 st. 10 lb. after the operation, and he held the gain for nearly three years. His appetite was good, he experienced the sensation of hunger, and he was able to eat the ordinary foods; but he had to take a rather longer time over a meal than in the days preceding his original illness.

The post-mortem examination for which Dr. Geoffrey Thompson had arranged was made on Feb. 1st, 1911, by Dr. M. J. Stewart, and his report is as follows: "The body is that of a somewhat emaciated man. All the tissues and organs exhibit an extreme degree of anæmia and the blood within the heart and great vessels is very watery in appearance. On opening the abdomen, the peritoneum is found to be free from disease, although there are some old fibrous adhesions between the first part of the jejunum and the operation cicatrix in the anterior abdominal wall, as also between the liver and the diaphragm. The cardiac end of the œsophagus is anastomosed to a loop of jejunum, which, for this purpose, has been brought through the transverse mesocolon. The proximal portion of jejunum and the duodenum, which ends in a cul-de-sac underneath the liver, appear to retain pretty much their normal dimensions, but at the seat of anastomosis and for a short distance beyond it, the jejunum appears to be slightly dilated. The whole intestinal tract, however, exhibits a marked degree of



Case of complete gastrectomy. Reproduction of photograph of specimen showing the condition found on post-mortem examination.

gaseous distension, and in the large intestine there are very numerous scybalous masses of considerable size. The liver is pale and somewhat fatty; the gall-bladder normal. The spleen contains a large and very old infarct, which occupies nearly the middle third of the organ. The kidneys are extremely pale and anæmic, while the capsules strip readily. The suprarenals are normal. There is no evidence of malignant disease in any part of the abdomen. A few of the retro-peritoneal glands are enlarged, but on microscopical examination they are found to be quite simple. The heart muscle is very pale and flabby. The valves are normal. The aorta and coronary arteries are quite healthy. There are numerous old adhesions on both sides of the chest. The lungs are extremely œdematous; they contain only a minimum of carbonaceous pigment. Microscopically the kidneys show well-marked though early fibrosis, involving both the interstitial tissue and the glomeruli. The chief points of interest are: (1) Complete absence of any recurrence or dissemination; (2) the very profound anæmia; and (3) absence of any striking jejunal dilatation at or near the site of anastomosis."

The photograph of the specimen brought to Leeds was taken in my laboratory. It shows well the anastomosis between the œsophagus and the jejunum, the slight dilatation of the jejunum, the blind rounded end of the duodenum, and the absence of any secondary growths.

Leeds.

AFTER-CARE.[1]

BY H. W. McCONNEL, M.A., M.B. CANTAB., M.R.C.S. ENG.,
SECRETARY TO THE KELLING SANATORIUM.

BY after-care I mean the looking after a patient and his surroundings after he has left a sanatorium or a dispensary. But it is of importance that the consideration of his future should be begun as soon as he commences treatment, and that the treatment itself should be modified accordingly. For it should be remembered that the object of the sanatorium treatment is not only to arrest a patient's disease and as much as possible to return him to work, but also to lead him, whether he knows it or not, to act as an educator of his own home circle and of all those with whom he comes into contact. He has not only to be cured, but he has also to spread abroad the principles of the open-air treatment by his example and future life. It must also be remembered that the social side of the circumstances of each individual patient is of great moment, and should be most carefully taken into consideration in the after-care.

After-care is of the utmost importance to the patient and to the nation. Indeed, it may be said that without it sanatorium treatment among the working classes loses much of its advantage for good, and is apt, moreover, to lead to a waste of public money.

There are two chief reasons why after-care is of such importance: (1) It allows the helpers—i.e., those that carry it out—to bring their influence to bear in the homes of the afflicted in a way that no other chance can; it gives them an entrance to these homes at a time when what they have to say and the lessons they have to teach will be fully considered; and (2) it supplements the sanatorium treatment, which is of necessity very incomplete.

Sanatorium treatment among the working classes is incomplete because it is almost always too short. The treatment is expensive and the length of time required for a permanent arrest is longer than the patient or his friends can afford; so in the majority of cases it is essential to supplement it by after-care if the good that has been gained is not to be lost again, and if the money that has been spent is not to be wasted.

Thus, having made out a case for after-care, I should like to consider very shortly what are the difficulties that are experienced by the patient himself or his friends both while he is at the sanatorium and also after he returns, and to mention at the same time how after-care can help to meet them, and then I should like to consider what is being done at present and what more can be done in the matter.

[1] A paper read before the National Society for the Prevention of Consumption and Other Forms of Tuberculosis on July 22nd, 1911.

The National Association for the Prevention of Consumption appointed a committee a few months ago to consider the subject of after-care and to make recommendations. This committee sent letters and questions to all the working-class sanatoriums—i.e., to 67, representing 4019 beds—and got more or less complete answers from all except one. It then sent similar letters and questions to a large number of Charity Organisation Society committees and kindred societies—to 228—and about half of these gave full answers and were therefore taken as typical; the information thus gained I have introduced into my subsequent remarks.

Now as regards the difficulties that can be dealt with by after-care, these fall under two heads: (1) those under the patient's control and (2) those not under his control. Those under his control are mainly (1) that he will not take advice and (2) that he is very slack in carrying out the lessons learnt. He will not take advice and delays in going to the sanatorium and thus turns an early case and one suitable for treatment into an unsuitable one from which a partial recovery at the best is all that can be hoped for. Again, after he has been at the sanatorium for a couple of months he begins to feel quite well, and he will not take the advice of those who recommend him to stay there for a longer time but insists on returning home and so loses his best chance of making the arrest of his disease permanent. Of course, I am not referring to the cases where want of money and home calls compel an early return, but rather to cases where these difficulties could be met, and where the chief obstacle lies in the cocksureness of the patient himself who imagines that because he feels well he is well. He is apt to give thanks and pity to the adviser; later he finds that he is wrong. In this difficulty an after-care committee can often control and influence where a casual remark has no effect.

Secondly, when he gets home, he is often slack in carrying out rules. When at the sanatorium, the patient learns the principles of treatment. He is taught how necessary open windows and fresh air are; how the food should be simple, well masticated and eaten slowly; how he should avoid rush and go early to bed; how he should rest before and after meals and should never sit down to meals when hot or tired; in a word, how he should make the best use of his off-time—i.e., of his out-of-work hours—in regaining and in keeping his health. He is taught all this at the sanatorium, and often when he gets home again he finds the windows shut and the house dusty, and instead of making an effort at once to bring about a change in the home, insisting on cleanliness and fresh air, he is apt to let things be. It is so easy to let things be and so difficult to alter old customs, but the disease has been arrested and the whole control of his home and his leisure hours lies with the patient. If he carries out what he has learned and what he has been taught he may keep well; if he lets everything slide he is qualifying for a relapse. If he is a bread-winner his whole family suffer through his fault and his gross slackness in the matter. Here, again, an after-care committee, by following the case up and by giving the patient advice at his own home, and by urging him to make use of the knowledge gained at the sanatorium, can do untold good, not only to the patient but also to those with whom he comes into contact.

The difficulties that are not under the patient's control are (1) incapacity and (2) the fear of infection.

1. The primary causes of incapacity are going to the sanatorium too late and staying there too short a time, and the result is incomplete arrest of the disease and liability to relapse; but our investigations show that it is probable that there is no greater difficulty in an ex-patient—i.e., in a patient from a sanatorium—getting employment than there is in the case of anyone else who is not fully capable from any other cause. Incapacity from phthisis is not more difficult to deal with than incapacity from any other reason.

2. Now a few words about infection, or fear of infection. It is necessary to mention the fear as well as the infection itself, for in the uneducated and unreasoning mind of the employer the fear has often more weight than the actual thing itself. The risk of infection, has, of course, been grossly exaggerated and is very slight indeed from a consumptive who is able to work, and from an ex-patient who has had sanatorium training it is almost *nil*, and is as nothing compared to that from a consumptive who has not had any hygienic teaching. It is founded on a misconception and a want of knowledge, and therefore must be combated by the after-care committee by every possible means.

It will be necessary to show the employers that to refuse work to an ex-patient because he has been to a sanatorium is not a very clever thing or a very reasonable thing. He is not dangerous, but, on the contrary, the fact that he went under treatment early and has got the disease arrested has removed all danger from him. If through fear of being turned out of his job he had worked on and on as long as he could till he broke down badly, then indeed there would have been danger to his companions. Once men know that their employers will take them back on their return from the sanatorium if they are capable, then directly they feel they are ill they will put themselves under treatment at once and will give themselves every chance of recovery; but as long as employers say to their men, "You have been to a sanatorium and therefore are dangerous," so long will these men hide up their disease and will remain a real danger to their fellow workers till they break down and go home to die. Combating these difficulties, especially with the employers, the after-care committee can do much to help, and remember, the employers want as much education as the employed.

Now a few words about the after-care work that is being done. The results of inquiries among the working-class sanatoriums show that about half—the exact figures being 36 out of 66—do after-care in some way, and the methods adopted fall under four heads: (1) Preliminary; (2) working patient scheme; (3) advice to patients; and (4) subsequent after-care.

1. Time does not permit of entering into details, but I may briefly state that by preliminary I mean the Gospel of Hope, the feeling that is engendered in all good sanatoriums among the patients that arrest and an active future are the object of their stay, and that to effect this they must work. They all work; all are as busy as busy can be, the loafer is not developed; they all look forward to arrest and future usefulness.

2. To help this still more the working patients scheme comes in. Selected cases are kept on; they give their work and get their board and lodging, and so are allowed a further period of treatment under more strenuous conditions, with time to get quite hard and time to look out for a suitable future. The nature of the work given differs in different sanatoriums. In some the men are employed in and about the place at work that brings into use their former experience and occupation. Thus, a carpenter is made to do his particular kind of work and a painter to paint, &c. At others attempt is made to teach definite trades that may be useful afterwards—French gardening, gardening, poultry farming, &c.[2] And thirdly, at some few sanatoriums a definite course of work and employment—a graduated system of labour—is proposed, with a view primarily of getting the patient hard and turning him out effective and less liable to relapse; thus, a gravel-pit is worked or ground is levelled—work of little use in itself but devised solely for the patient's improvement.

3. Under "Advice to Patients" is included the general lectures and teachings, and the individual advice. The latter is best done after a month's stay, when the prognosis is the more clear and the future can be better estimated. Each case is dealt with separately and on its own merits, and the possibilities considered, taking into account the home ties and the surroundings, and recognising the great advantages of the old employment, because it is the one that is known and therefore the easiest, and recognising, too, that a bad employment is better than none at all, for none means starvation and therefore relapse. It must always be remembered that the bad effect of what seems a hopelessly unsuitable employment may be neutralised by the correct use of the remaining 16 hours which are absolutely under the patient's control. Usually, also, further advice and a useful leaflet are given just on leaving, and each and every one is made to understand that when they leave they must avoid excess, must lead a quiet, sensible life, and always carry out the principles of open-air treatment, fresh air, plain food, and rest before and after meals.

4. And then, finally, the subsequent after-care—the looking after the patients after they leave. Experience shows that not much can be done in this way by the sanatoriums. It is possible, indeed, by postcards and Christmas cards to keep in touch with the ex-patients, and it is desirable to get them to call periodically for advice and examination, but this is about all that can be done. To follow the patients up after they leave and to keep a systematic hold on them are beyond a sanatorium's powers. This work must now be left to the senders—to those who sent the patient to the sanatorium: they must now step in and take charge. All ex-patients need a friend, and it is very pleasant to be able to state that the societies—the Charity Organisation Society and similar societies—mostly do help in this way; that out of 102 that send patients to sanatoriums, 83 look after them on their return, in some way mostly through the ordinary visitors; six have special visitors and six others after-care committees, and about a third make special efforts to get employers to coöperate in finding work, &c.

This, then, is the present position: 1. After-care is an essential to meet the various difficulties. 2. The sanatoriums, either by special after-care committees, by lectures or by individual advice, do much to help and to start the patient off well. 3. A large proportion of the senders are already organised to do what they can to carry on the work. But it is here, in the link between the sanatoriums and the senders, that the failure comes in; there is apt to be a hiatus, and the link is apt to be missing; there is a want of continuity in the advice given, and much good is lost by want of coöperation of the various advisers.

After careful investigation of the situation the National Association for the Prevention of Consumption has decided to meet this difficulty by the following recommendations, believing that much better results will be arrived at by some uniform scheme. The recommendations are as follows:—
A. To advise both the sanatorium authorities and the senders: 1. To recommend their patients (*a*) to return as much as possible to their old employment; (*b*) to make the best use of their leisure time; and (*c*) to carry on in their own homes in every possible way the principles of the open-air treatment learnt in the sanatorium, both as regards themselves and their friends. 2. To see that each patient has a leaflet of instruction in his own home. 3. To try to convince employers that the risk of infection from an ex-patient is very slight and as nothing compared with that from a consumptive who has not had any teaching.
B. (And this is the important recommendation.) To ask the superintendents of all sanatoriums for the working classes, with a view of getting continuity of advice, to secure in some way that advice and help be given to patients while at the sanatorium about their future life and work, and to arrange to give, if asked, a report or memorandum of this advice to the sender.
C. To ask all Charity Organisation Society committees and kindred societies who send patients to sanatoriums to look after the cases they have sent on their return; and to get and make use of the sanatorium's report and advice about each patient.
D. *As regards London*, to ask the Medical Advisory Subcommittee of the Charity Organisation Society to appoint representatives in each borough who as private individuals and not as Charity Organisation Society workers will undertake, with the permission of the patients, to visit the homes of the patients notified to them by sanatorium authorities as having come to sanatoriums independently of societies, and who also will undertake on the patient's return to give advice when needed.
E. *As regards the provinces*, to get some similar scheme of representation started according to the need of the place and in the manner best suited to it. The medical officer of health's advice may well be asked in the matter. It is hoped that something on these lines will commend itself to those interested, and it is hoped to start work energetically in the autumn to carry them out.

Special attention is being given in this congress to the National Insurance Bill, and if a reference is to be made to it in the consideration of after-care the following two thoughts may be allowed:—

1. After-care is mainly dependent on individual effort acting in individual cases, and there is a great danger in sanatoriums supported by State funds that this individuality of the workers will be hampered and checked, that private interest and work will be superseded by officialism which will not only be more expensive but less effective, and that the little touch that just makes all the difference between good results and exceptional results will be found wanting.

[2] Here I should like to mention that the garden in the women's quarters at Kelling is being turned over to two girl gardeners, who are not only doing it very well but by their increased health are showing what such work can do for such cases in the way of cure.

2. The working patient scheme where patients are employed in and about the sanatoriums, possibly for a small wage, will be hampered because, unless the Bill is amended, these workers will have to be insured and the sanatoriums will have to pay the insurance, and so a scheme which is only in operation for the patient's good will lead to a larger loss to the sanatoriums than it does at present.

Possibly these difficulties can be removed (1) by working the State-paid sanatoriums through the existing sanatorium machinery and so keeping its individuality; and (2) by freeing all working patients whose work is part of their treatment from the action of the Bill; but unless this is done it is impossible that sanatoriums can have the satisfactory results that they do at present.

Norwich.

EXCESSIVE LOCAL PERSPIRATION.

AN ACCOUNT OF THE SUCCESSFUL TREATMENT OF FIFTEEN CASES.

BY A. HOWARD PIRIE, M.D. EDIN.,

CHIEF ASSISTANT IN THE X RAY DEPARTMENT AT ST. BARTHOLOMEW'S HOSPITAL.

MY attention was first directed to this subject about five years ago, when I noticed that after a long-continued series of sittings under X rays the patient ceased to perspire on the part treated. Since that time I have had 20 cases of excessive perspiration to treat. Nine of these have been qualified medical men. In every case which has been fully treated the rays have produced their effect on the sweat glands, and either entirely stopped their action or reduced it to less than normal.

The parts I have had to treat have been: the face, 2 cases; armpits, 10 cases; hands, 9 cases; and feet, 1 case. One case included hands, face, and armpits. In two cases a cure was got after only two applications and no more sittings were given, but usually from three to five have been required. The number of treatments required depends on the dose given. In the two cases which were cured by two sittings both suffered from the effects of too large a dose of X rays (pain, irritation, blistering, and redness), and since these two cases the others have been done by the longer method. I believe six sittings of one pastille dose each at intervals of one month is the best treatment, as it causes absolutely no discomfort and the patient runs no risk.

The rationale of the treatment is, I believe, as follows. When an X ray photograph of the thigh is made the negative shows the bone lighter in colour than the surrounding tissues, because the bone, being denser, has absorbed more X rays than the surrounding tissues. Looking at a normal cell and at a karyokinetic cell, we see that in the latter the chromatic filaments are more condensed, and these denser filaments absorb more of the rays than the normal cell does. There is a limit of X rays which has no effect on a cell. More X rays will stimulate the cell, still more will damage it, and still more will destroy it. The greater absorptive power of the karyokinetic cell to X rays makes it more vulnerable, so that the dose of X rays which will just not kill a normal cell, kills a cell undergoing division. The dose required for this is, I believe, a little more than a pastille dose, so that by giving one pastille dose each month for a period of six months the karyokinetic cells (especially those of slow growth) are destroyed. This principally affects the hairs, sebaceous and sweat glands.

I have had the opportunity of having a piece of skin so treated examined in the Pathological Laboratory at St. Bartholomew's Hospital, and many sections cut from it were examined. The report states:—

April 28th, 1911. Examination required: Skin after treatment by X rays. Pathological report: The skin was very difficult to dehydrate. On section it appeared normal as regards the epithelium, except that the cells were difficult to stain and much keratinised. No hair follicles, sebaceous or *sweat glands* found. The tissue underlying the surface epithellum was composed of dense fibrous tissue. H. G. B.

Kolipinski has reported one successful case of hyperidrosis axillæ treated by the thermocautery. The result was got by producing burns of the second and third degree. Major F. J. W. Porter, R.A.M.C., recommended dissecting away the skin of the axilla in order to stop perspiration. No other method but these and X rays have been found efficacious in stopping perspiration. Drugs are useless as a permanent cure.

In treating the hands or armpits I get all parts of the surface of the skin equally exposed to the rays by means of a delivery tube which has a firm base of celluloid. The celluloid is a part of a sphere whose radius is 24 cm. The source of the rays is placed at the centre of this sphere and the hands are pressed firmly against the celluloid. Thus all the parts of the hands which touch the sphere are exactly 24 cm. distant from the source of the rays. A barium platinocyanide pastille is placed 12 cm. from the source of the rays and another pastille is placed on the hands. The dose can thus be measured by Sabouraud's method and at the same time by the control on the skin.[1] Another control I use at the same time is the milliampère minute method with a water meter. The celluloid absorbs a small quantity of rays, and I trust mostly to the pastille on the skin and look on the other two methods as controls.

Pusey in 1903 and Bulkley in 1904 reported cases of hyperidrosis in the axilla which were improved by X rays. Engmann was the first to recommend the application of a dose which would produce an erythema. Lanari recommended in treating the palms of the hands that the surface should be divided into four areas and each area treated by itself. The dose to each area he recommends is 8X—i.e., nearly two pastille doses—so as to produce redness, swelling, and skinning. The skin is shed in large flakes, leaving red, smooth skin underneath. The skin becomes normal after several weeks. He considers one such application sufficient for a permanent cure, and reports a perfect result in one case a year after the treatment. In one case in which I carried out this treatment the perspiration was not checked. In other two cases (Cases 7 and 8) such a dose had the desired effect, but caused much discomfort, and I do not recommend so large a dose. Stover in 1905 and Kromayer in 1907 reported cases of hyperidrosis treated by X rays.

I can only find reports of isolated cases, and I therefore think that a report on a series of 20 cases should prove of interest. They are the following:—

CASE 1.—The patient, about 45 years old, had suffered from excessive perspiration in his armpits for the last 30 years. He was very definite in his description of its type, which was as follows. It began after 10 A.M. and continued till about 6 P.M. During the evening and in bed he was not troubled by it. Cold and worry aggravated it; therefore he disliked driving on a cold day and writing letters which required much thought. Treatments by X ray were given on May 25th, June 19th, and July 24th, 1909. On the last date he said the perspiration was less. He noticed that when he perspired in the morning his shirt was wet, but that it dried again before evening, whereas it used to remain wet all day. On August 28th he reported that he no longer required to change his undershirt while dressing for dinner, provided he had not been working hard during the day. Another treatment was given on August 28th. On Sept. 19th he reported perfect comfort except on extreme exertion.

On June 23rd, 1910, he wrote to me: "I am glad to say that my arms are still quite comfortable. Even yet I have not got used to the indescribable feeling of comfort. There are many people, especially women, who ought to have your treatment." On April 12th, 1911, he came to see me for another purpose, and I noticed that both armpits were quite dry. There were telangiectases in the lower half of the right axilla. The left axilla had no telangiectases, and the hair was thin.

CASE 2.—A surgeon, of about 25, suffered from excessive perspiration over his face, hands, and armpits. He was of a nervous disposition, and his perspiration was of the ordinary nervous type, made worse by excitement and lessened by cold. His father also suffered from it. Having so many areas to treat, many sittings were required from July 16th, 1909, till March 25th, 1910. The face was the most troublesome area, and caused me considerable anxiety, but, in the end, hands, armpits, and face ceased to sweat profusely, and have continued so since. In June, 1911, I heard from him, and he remains quite comfortable.

CASE 3.—Dr. —— came to me on May 17th, 1909, suffering from excessive perspiration in the armpits. It had troubled him all his life. On touching the armpit of his shirt and coat I found them quite wet. He showed me what he called his high water line—i.e., the line to which the perspiration on his coat extended. At this line a white deposit of the salts of perspiration lay owing to evaporation. He remembered this line on his Eton jacket at school 20 years before. The perspiration was made worse by excitement and heat. It was very troublesome in cold weather. It rotted his clothes. Treatments were given on May 17th, June 19th, and July 2nd, 1909, and on the last date he was improved so far that each day after midday perspiration ceased, and his shirt which got wet in the morning became dry in the afternoon. I noticed his left axilla sweating while his right did not. Further treatment was given on Sept. 17th and since then the patient has been quite comfortable

An interesting thing happened after the first application of the rays on May 17th—viz., he did not perspire for the rest of the day. He did not remember to have ever before experienced a day without perspiration. On July 24th, 1910, 11 months after his last séance, he described his case to me as one of "unqualified and permanent cure." I have not heard from him since, but I believe he remains cured.

CASE 4.—A surgeon, of about 40, came to me at the end of 1909, complaining of perspiring hands. The perspiration was made worse by exertion and excitement. He had suffered from it as long as he could remember. It troubled him most while attending a confinement or

[1] See Archives of the Röntgen Ray, 1911, for description of this method.

doing an operation owing to his fear of producing sepsis from his own rough and cracked hands. His hands were very rough and cracked from his continual use of 40 per cent. formalin in which he soaked them in order to get temporary relief. X ray treatments were applied at the end of May, June 30th, July 28th, and August 29th, 1909. On the last date he said the perspiration was decidedly better, and I noticed his hands were drier than my own. He had been using formalin. No more treatment was given till March 18th, 1910, owing to the distance he had to come for the treatment—over 100 miles—and due to his professional duties. Perspiration had been so little since the last treatment that he had been quite comfortable. A treatment was given on March 18th and July 8th, 1910, and since then he has had no more trouble from perspiration. On June 7th, 1911, he writes: "Yes, my hands are a great success and no trace of perspiration except, of course, between the fingers, and there very little. I believe the sweat glands are destroyed and that the cure is permanent, for the recent hot weather would have found it out were it not so.

CASE 5.—A physician, of about 40 years of age, had suffered from excessive perspiration in his armpits as long as he could remember. It was made worse by exertion or excitement. Cold did not increase it. He was comfortable during the evening if he was resting, but very uncomfortable all the rest of the day. X rays were applied on Oct. 12th and on Nov. 15th, 1910. Both these treatments were nearly double normal dose, and a month after the last he was so comfortable that he wished no more treatment. He came again on March 1st, 1911, and had another treatment, though he was perfectly comfortable. His comment on April 5th, 1911, on his own case was, "I consider the cure perfect. The comfort can only be appreciated by one who knows."

CASE 6.—A surgeon, of about 30, had suffered as long as he could remember from excessive perspiration in the armpits. It did not usually trouble him during the evening and never during the night. It was made worse by cold and worry. He had tried many external applications for it, including formalin, without effect. Rubber shields were useless, and acted like a poultice. A first X ray treatment was given on Feb. 26th, 1910. This produced a slight reaction and some epilation. When I saw him a month later the perspiration was still excessive, and I watched it collecting into drops. On March 10th another treatment was given, which was followed by marked improvement. The perspiration had so much decreased that it did not soil his shirt. Another was given on May 10th. On July 27th I found both axillæ pigmented, the right completely hairless and the left hairless in its upper half, but not epilated in its lower half. He has suffered no inconvenience from perspiration since July 27th. In November I had an opportunity of examining his axillæ and found the right was absolutely dry, and the left nearly so. His left was drier than my own axilla. It perspired so little that his undershirt was never damp. He remains cured.

CASE 7.—A single lady of about 21, suffered from excessive perspiration in the armpits. It was made worse by excitement and exertion, but it was just as bad in cold weather as in hot. She came to me and had a first treatment on Sept. 28th, 1910. When she lay down on the couch for treatment the perspiration ran from her armpits and soiled an area about six inches in diameter on the couch. A double dose was given on Oct. 25th, and this was followed by a severe reaction. I did not see her for the next three months, during which she suffered from several "boils" in the axillæ which had to be lanced. She had during the past year suffered from boils, and had undergone vaccine treatment for them before she came to me. After the reaction subsided the perspiration ceased in both armpits and no further X rays were required as the patient was quite comfortable. On Jan. 17th, 1911, she reported that her left armpit is always dry, while the right perspires very slightly. Her blouse is never wet, and she takes no precaution to keep it dry.

She came to me at my request on June 7th, 1911, and I found the left axilla had a few hairs in its deepest part, but no telangiectases and slight pigmentation. The left axilla felt quite dry to the touch, though the temperature on June 7th was about 70° F. in the shade. The right armpit had rather more hair than the left and was slightly damp, though not so damp as a normal axilla on a hot day. The contrast of her condition now with what it was when the perspiration ran from her axilla and soiled the couch during her first treatment is very marked.

CASE 8.—A nurse, aged 32, suffered from excessive perspiration in her armpits since 18 years of age. It was made worse by heat, exertion, and excitement. When she lay down on the couch for treatment I saw the perspiration trickling from the armpits down the sides of the chest. A first treatment was given on August 9th, 1910. On Sept. 7th a double dose was given, which caused a severe reaction. On Oct. 13th the reaction began to pass off and perspiration completely ceased. The hairs fell out completely from the right armpit. On examination about six months later I found the armpits quite dry, nearly hairless, and much pigmented. On June 7th, 1911, I heard that the patient had had no more trouble from perspiration. After the double dose herpes zoster appeared about the level of the seventh intercostal nerve. This is the only case in which I have seen herpes appear during X ray treatment.

CASE 9.—A married lady of about 35 suffered from excessive perspiration in her armpits as long as she could remember. The perspiration soiled her blouse very badly, no matter what precautions she took. Treatment by X rays were given on July 26th, August 30th, Sept. 26th, and Oct. 24th, 1910. After the last date the right armpit ceased to sweat and the left sweated still a little. A last treatment was given on Nov. 21st, and since then she has remained quite comfortable.

CASE 10.—A single lady of about 25 suffered from excessive perspiration on her hands. She could not write without soiling the paper nor do needlework without soiling the work. When I looked at her hands the lines in the palms were wet with perspiration. Treatments were given on Dec. 1st, 1910, and Jan. 5th, Feb. 2nd, and March 2nd, 1911. On March 30th she reported that her hands no longer perspired, but that the tips of her fingers still troubled her. Treatments were given on March 30th and May 4th. On the latter date she said she was quite comfortable. The palms were always dry and the tips of her fingers usually were so, but sometimes not. The skin between the fingers remained moist, but not sufficient to cause any inconvenience. She has remained perfectly comfortable since.

CASE 11.—A gentleman of about 40 suffered as long as he could remember from excessive perspiration on his face. It came on badly on exertion, but especially on excitement. So much did it annoy him that he shrank from attending social functions and taking any public positions. Treatments by X rays were given on Nov. 8th and Dec. 8th, 1910, and on Jan. 10th, 1911. On the latter date he reported that he had during the last fortnight attended two dances and perspired less than the other men did. A last treatment was given on March 7th, and since then he has been quite comfortable. On severe exertion he still perspires, but not otherwise. During his treatment I painted his eyebrows with a thick bismuth paste and covered his moustache and hair with lead. The roots of the eyelashes were also covered with lead.

On June 7th, 1911, he wrote me as follows: "The X ray treatment has been a great success. It has stopped the extreme sweating on my face. It only breaks through after exercise in the heat very slightly under my hat at the roots of my hair, just at the nostrils and under my lower lip, and, of course, in the eyebrows a bit, as they were protected. But the whole of it is of no consequence whatever compared with what it used to be. I was down for three days at Bisley in the intense heat and while most other men were streaming on the face I was merely moist."

The parts which he mentions which still sweat are those which were partly protected during the treatment. In treating the face I divide its surface into four areas, and direct the perpendicular ray on each side of the face at a point an inch and a half above the external canthus and at the anterior border of the masseter on a level with the mouth. The areas are treated as for ringworm without shielding the contiguous areas. Four pastilles are fastened in position on the skin with gum before beginning the treatment. During the exposure of one area each other area is getting a little X rays, therefore less than a normal dose is given to each area. The exposures are made so that at the end of the treatment the four pastilles have changed to an equal tint. Thus the whole face gets an equal dose. The treatment made the patient's face appear as if he had been sunburned, but on looking into the eyebrows one could see his original colour. The bismuth paste acted very well and no epilation was caused in parts protected. Epilation of the beard took place. After two months he required to shave as before.

CASE 12.—A student, of about 21, whose hands perspired as long as he could remember. They perspired even in bed. He had tried zinc sulphate, liq. plumb. fort., lead plaster, and dusting powders with no relief. Treatments were given on Oct. 8th, Oct. 29th, and Nov. 19th, 1910. After the last treatment his hands skinned. On the last date I noticed the thenar eminences were dry and the rest of the hands were moist. On Dec. 22nd I noticed the hands were all dry except the fingertips and between the fingers. Since then he has been comfortable and has had no more treatment. A last treatment was given on Dec. 22nd. On June 16th, 1911, he told me that in very hot weather his hands still perspire, but in ordinary weather they are generally dry. The ball of the thumb (which received a greater quantity of X rays during the treatment) does not now perspire under any conditions of temperature.

CASE 13.—A professor of medicine suffered from excessive perspiration on his feet with the result that his feet were always cold. This condition began while standing in the pathological laboratory. On walking 200 yards his feet were soaking. His feet were dry on rising in the morning, but they remained damp till he went to bed. He had two applications at intervals of 14 days in Edinburgh, from Dr. Norman Walker, who sent him for further treatment. In February, 1911, I gave him one treatment and shortly after he reported to me that the condition was much improved. Before he could have another treatment he had to go abroad, and I have not heard of him since.

CASE 14.—A surgeon of about 40 years of age suffered from excessive perspiration in the armpits as long as he could remember. It was made worse by heat and exertion. He also perspired in cold weather. He treated himself by X rays, but unfortunately he produced a bad burn not only on his right armpit but also on his right elbow. This took place in April, 1910. On Feb. 8th, 1911, he came to me for the completion of the cure. I protected the parts that had been burned (the upper half of the right axilla) and the right elbow with lead rubber, and exposed the lower half of the right axilla. Treatment was given to both axillæ on Feb. 8th and March 8th. Although the old burns were carefully protected by the heaviest lead rubber the ulcer broke down over an area of the size of a pin's head and caused much pain. Treatment was therefore stopped. The right axilla is now quite free from perspiration under all circumstances, and the left does not perspire sufficiently to soil his shirt.

CASE 15.—A girl of 14 perspired so much on her hands that it soiled her needlework. The perspiration was less when she was cold and greater when she was hot. The terminal phalanges perspired most. A treatment was given on May 18th, 1910, and another a month later. In June, 1911, I heard from her mother that the patient had not been able to come for further treatment as she had had to leave London, but that her hands were much improved.

Epitome of Result of X Ray Treatment of 15 Cases of Excessive Local Perspiration.

Number of case.	Part treated.	Number of treatments.	Result.
1	Armpits.	5	Cured.
2	Face, armpits, hands.	5 to each area.	,,
3	Armpits.	4	,,
4	Hands.	5	,,
5	Armpits.	3	,,
6	,,	4	,,
7	,,	2	,,
8	,,	2	,,
9	,,	5	,,
10	Hands.	6	,,
11	Face.	4	,,
12	Hands.	4	,,
13	Feet.	1	Improved.
14	Armpits.	2	,,
15	Hands.	2	,,

Note.—Those cases cured in two sittings had discomfort caused by

reaction from the X rays. Those cured in five and six treatments had no discomfort from the treatment and no reaction except slight pigmentation.

The next five cases are still under treatment as they have just come to me lately, viz.:—

CASE 16.—A lady whose hands perspire so freely that I have seen the perspiration fall from her finger-tips five minutes after she has thoroughly dried her hands.

CASE 17.—A doctor who shrinks from his professional duties owing to his perspiring hands.

CASE 18.—A worker in fine steel instruments who has to wear gloves to prevent his perspiration rusting the steel.

CASE 19.—A lady whose hands perspire so much that she soils her work.

CASE 20.—A doctor whose armpits perspire profusely.

These cases, I expect, will yield as the former ones have done.

Excessive local perspiration cannot be classed as a disease, but to one afflicted with it it is a real infirmity. A surgeon with perspiring hands runs a risk of infecting a wound. A physician with perspiring hands leaves his patient's wrist wet after feeling the pulse, and has the chagrin of seeing his patient drying the wrist. When the armpits are affected clothes are soiled and rotted by the perspiration, and the patient is uncomfortable from wearing wet underclothing. Cold feet from socks wet with perspiration is another form of annoyance.

All these conditions can be cured by X rays. In my experience every case which has been fully treated has been a complete success, and I can thoroughly recommend the treatment. When perfectly carried out the patient suffers no discomfort and there are no bad after-effects.

Harley-street, W.

PRESENTATION TO A MEDICAL PRACTITIONER.—At the Exmouth (Devon) Dispensary on July 24th Mr. Oliver Eaton, L.R.C.P. Lond., M.R.C.S. Eng., D.P.H. Camb., was presented with a silver-mounted pipe, suitably inscribed, by the local detachment of the British Red Cross Society in appreciation of his services as honorary lecturer.

A NEW FORM OF TROCHISCUS.

BY SIR JAMES SAWYER, M.D. LOND., F.R.C.P. LOND., F.R.S. EDIN.,

CONSULTING PHYSICIAN TO THE QUEEN'S HOSPITAL, BIRMINGHAM; EX-PROFESSOR OF MEDICINE IN THE BIRMINGHAM MEDICAL SCHOOL; LATELY LUMLEIAN LECTURER AT THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE τρόχισκος of Galen (A.D. 131-201, next to Hippocrates the greatest physician of antiquity) was not the officinal flat, punched-out lozenge of present-day pharmacists, but it was a small globe or ball, may be of soap, may be of sugar, a pastille sometimes, in the sense of being a medicated "drop" of sweet confectionery. To some such ball, as a medicinal vehicle of frequent use, medicine may now well return and find therein abundantly suggestions of therapeutic usefulness. For such purposes I suggest the assimilation into medical practice of the excellent pharmacological basis afforded us by the popular modern sweetmeat known as the "chocolate cream."

Ten years ago I published a paper on medicated lozenges,[1] and seven years ago I included a revised and extended version of the same paper in a book of mine upon subjects in a physician's practice, addressed to my medical brethren.[2] My present suggestion is an outcome of my continued and further attention to this very useful mode of medication in my therapeutic work. Surely the prescriber who ordains an efficient and grateful trochiscus will well fulfil the third article of a very authoritative precept of medical practice—namely, *curare cito, tuto, et jucunde.* Horace's apostrophe, "*qui miscuit utile dulci*"[3] may be held of a physician who can prescribe in his own magistral formula—that is, in a formula which is appropriately varied accordingly as he finds the individual therapeutic indications afforded by each particular patient—a skilfully medicated trochiscus, combining efficient remedies in the pleasing form of a delectable sweetmeat.

Many, indeed, are the remedies which an experienced and experimented prescriber may choose for exhibition in such a form of trochiscus, and so for direct application through the agency of that vehicle to the mucous membranes, and even to the deeper parts, of the lips, mouth, tongue, fauces, nares, throat, œsophagus, stomach, and further on in the alimentary canal, and of the respiratory passages below the pharynx, and also for their general as well as their local physiological actions and therapeutic effects. In many maladies of the oral cavities, fauces, tonsils, uvula, velum palati, pharynx, gullet, in some diseases affecting the larynx, in some bronchial and in some other pulmonary disorders, and in some other morbid conditions which may indicate the accurate exhibition of drugs (all of which conditions can alone be contra-distinguished by the fully trained member of our faculty), the basis and form of a trochiscus supply to us a convenient, agreeable, and effective vehicle for our particular selection from a large repertory of remedies.

It may be useful to recall that we owe our present therapeutic use of "lozenges" largely to the old Edinburgh Pharmacopœia. Early in the century last past that veteran therapeutist, Dr. Paris, declared that "trochisci, troches, or lozenges" were then generally regarded as objects rather of the art of the confectioner than of that of the pharmacist, and so neither the London nor the Dublin Royal College of Physicians condescended to notice them, while the Edinburgh Pharmacopœia gave several formulæ for their preparation. Dr. Paris held such preparations as undoubtedly useful in medical practice, not only in the officinal forms but also in certain magistral combinations, for which latter he published some valuable suggestions in his classical Pharmacologia. Since his time many clinical considerations, based upon advances in our knowledge in physiology and in pathology, and the employment of certain improved diagnostic instruments of visual research, have enlarged the use of medicated trochisci. The British Pharmacopœia gives 17 formulæ for trochisci, these medicaments being made up variously with a "fruit basis," with a "simple basis," with a

[1] Brit. Med. Jour., Nov. 30th, 1901.
[2] Contributions to Practical Medicine, fourth edition, 1904.
[3] De Arte Poetica, l. 343.

"rose basis," or with a "tolu basis." Besides these officinal preparations, many others of a like kind are to be found in our hospital pharmacopœias, while there are many others in popular use, some of them of secret composition, and some of them under proprietory exploitation, with all its baneful consequences.

In my present communication, as in others I have made upon the subject, I aim at encouraging my professional brethren to prescribe medicinal trochisci in their own magistral formulæ, and I desire to draw their attention to a new vehicle of the kind which I have found useful in practice—namely, the "chocolate cream." As we know, chocolate is made by triturating in a heated mortar the roasted seeds of the Theobroma cacao, freed from their husks, with an equal quantity of sugar (saccharose), and making the mixture into a paste with water, having flavoured it variously, as with vanilla or with cinnamon, and the "cream" is made by filling a small globular envelope of this mixture with a small portion of milk which has been mixed with sugar and evaporated by the aid of fire to a pasty consistency. It is this latter paste which should be medicated from our prescriptions by the pharmacist. Some skilful members of the craft have succeeded well in carrying out my own wishes to such purpose. Such medicated trochiscus we may prescribe, thus:—

℞ Menthol, gr. ½.
Ol. eucalypt., m½.
Pastæ lactis,
Pastæ nuclei cacao, āā q.s.
Fiat trochiscus, sec. artem.

Or the pasta lactis in each trochiscus may be medicated by the addition to it of a grain or two of borax, or half a grain of sulphate of zinc, or a minim of oil of turpentine, or of oil of cajuput, or half a minim of oil of anise. The various clinical indications for the choice of these and of other medicaments which may be exhibited in the vehicle I now propose are well known to our profession and are alone distinguishable by one of us, so that any enumeration of the symptoms which suggest the use of such remedies is unnecessary in any communication from me, and in the public interest, for reasons which will at once occur to us, such enumeration would be undesirable.

Perhaps the trochisci I have now described might be called cremules and, Latinised, cremulæ Wnen quickness of preparation is to be wished for unmedicated ones can be medicated readily by remedies which are liquid in their form, by injecting a minim or so of the medicament into the centre of a "simple" cremule, by the aid of a hypodermic syringe.

Birmingham.

Reviews and Notices of Books.

Geschichte der Medizin (*History of Medicine*). By Dr. MAX NEUBURGER, Professor of the History of Medicine in the Imperial and Royal University of Vienna, &c. Vol. II., Part 1, second half. Stuttgart: Ferdinand Enke. 1911. Pp. 233–528. Price M.8.20, or 8*s.* 3*d.*

THIS instalment of Professor Neuburger's excellent History of Medicine deals with a conspicuously barren period in the existence of the healing art—a period for the most part of apparent retrogression rather than of progress. Nevertheless, it is interesting to trace the rivulets derived from Greek and Arabic sources which trickle through the dreary morass of darkness and superstition.

After a few pages devoted to Celtic and ancient German medicine, the author proceeds to deal with the art as it existed in the early Middle Ages. Throughout the greater part of Europe medicine was chiefly practised at this time by priests and monks, but in some parts, notably in Southern Italy, lay practitioners were not extinct, and the seeds were kept alive which were some centuries afterwards to develop into the School of Salerno. A name of note at the beginning of the sixth century is that of Anthimus, who exhibited some originality of thought and wrote sensibly on the regulation of diet in disease. It was a time of war, pestilence, and famine, in which the cloister alone afforded a safe asylum for any kind of learning; and in default of possibilities for research we must be grateful to the monks for their services in copying and handing down to us the works of the great writers of earlier times. Among the preservers of medical writings must be noticed Cassiodorus, who was first a statesman and then a monk, and Benedictus Crispus, a bishop who about the beginning of the eighth century wrote in bad Latin hexameters a compilation of remedies. Monkish medicine, however, naturally tended to superstitious observances, worship of relics, and miracle-working. In the South of Italy study of the later Latin writers on medicine prevailed and the construction of medical epitomes was much practised in the eighth century. Some of the rules for the visiting of the sick and for the management of the patient and his friends drawn up at this period have a curiously modern air. Under Charlemagne the foundation of hospices and infirmaries for the sick was encouraged, and the medicine of his reign is associated with the name of Alcuin, who carried on the traditions of the Anglo-Saxon school, which had been adorned some half century before by the Venerable Bede. In the tenth century a school of some note existed at Chartres, and medicine was largely practised by Jewish physicians. Lepers were segregated, mainly on religious grounds, and exorcism was frequently practised.

The eleventh and twelfth centuries saw the rise to eminence of the celebrated school of Salerno, famous among whose teachers were Gariopontus, Petroncellus, Alphanus, and Trotula—the last of whom is called "*sapiens matrona*," a learned lady. Little was done in these times in the way of extending scientific knowledge, but the ancient authors were studied and translated, and compendia were made for practical use. In the twelfth century we find various forms of madness recognised as diseases of the brain and assigned to affections of different parts of this organ, while the surgical skill attained by some members of the school of Salerno is shown by the advice to suture the ends of divided intestine over a hollow cylinder of elder wood. Schools of less note flourished also at Bologna and Montpellier. A distinguished scion of the latter was Arnaldus of Villanova, who appears to have been, not only a learned man, but a sensible physician. Gradually, however, during this century the growth of scholasticism and formalism submerged all original thought. The worship of Aristotle as an infallible authority left no room for personal observation, and throughout the fourteenth century stagnation everywhere prevailed. Even when the opportunities for fresh knowledge occurred, as in the revival of the practice of human dissection, the desire to confirm the accepted doctrines precluded accurate observation and scientific advance. In medical practice inspection of the urine was the main diagnostic measure, and bleeding and purgation were the chief methods of treatment. The belief in astrology took the form of placing various regions of the body under the influence of different constellations, and figures illustrating this superstition accompany those showing the superficial veins suitable for venesection in the manuscripts of this epoch. Some of these curious figures are reproduced in Professor Neuburger's book.

It is greatly to the credit of the learned author that he succeeds in retaining the reader's interest in his account of the fortunes of medicine during the depressing period which is dealt with. The book is in every respect worthy of its predecessors, of which we have expressed on former occasions our high appreciation, and we look forward with keen expectation to the appearance of the concluding volume or volumes of this most scholarly and authoritative History of Medicine.

Regimen Sanitatis: The Rule of Health. A Gaelic Medical Manuscript of the Early Sixteenth Century, or perhaps older, from the Vade Mecum of the Famous Macbeaths, Physicians to the Lords of the Isles and the Kings of Scotland for Several Centuries. By H. CAMERON GILLIES, M.D. Printed for the author by Robert Maclehose and Co., Limited, University Press, Glasgow. 1911. Pp. 139.

To Dr. H. Cameron Gillies thanks are due for this most interesting and admirably got-up book, which is the first definite effort to restore to the light the Gaelic medical manuscripts which have so long lain mouldering in oblivion. *Regimen Sanitatis* (or the Rule of Health), an old Gaelic medical manuscript of 62 vellum folios, was discovered in the British Museum by Dr. Gillies. It belonged to John Macbeath (his name may be taken as representative of the whole family, others doubtless contributing), who kept a note-book, or *Vade Mecum*, in which he jotted down the sum and essence of his reading of all that was best in the medical literature of Greece and Rome and Araby, mingled with his own comments and observations, which were based on a wide personal experience. This note-book was set down in the Scottish Gaelic of the time (the early sixteenth or even fifteenth century). It was never intended for publication, but was simply a sort of practical *liber memorabilium*, such as is kept by many modern members of the medical profession. MacBeath gave his manuscripts over to a professional Irish scribe—Aodh O'Cendainn—so that the substance might be written in the best and most compact form, and that is how they are now extant—thanks to Dr. Gillies. The MacBeaths seem to have read the best that was available in their time, and in their writings we meet such names as Avicenna, Averroes, Joannes de Vigo, and Hippocrates.

Part of the text of the *Regimen Sanitatis* is based upon *Rosa Anglica seu practica medicinae*, a work written by John of Gaddesden, who was taught in the Montpellier School and who was a graduate in medicine of Merton College, Oxford, and a Court physician. The *Rosa Anglica* was so popular that it was reprinted up to the end of the sixteenth century. The substance, and indeed the essential character, of the *Regimen Sanitatis* is based upon the famous rhyming Latin poem—a popular work intended for the laity—by Joannes de Meditano, *Regimen Sanitatis Salerni*. It is said that William of Normandy (afterwards William the Conqueror) went to the famous medical school of Salerno—nicknamed "Civitas Hippocratica"—in search of health, and this book by Meditano, which had an immense reputation in the Middle Ages, being translated into most European languages, was addressed to Robert, son of William the Conqueror—"Anglorum Regi." Hali's Compendium, which Constantinus Africanus of Carthage, who studied at Monte Cassino, rendered under the title of *Pantegni*, is referred to in this Gaelic manuscript; and undoubtedly the MacBeaths were greatly influenced by an important work which they possessed—*Practica seu lilium Medicinae* of Bernard Gordon, a Scottish teacher at Montpellier in the early part of the fourteenth century. The MSS. of the *Regimen Sanitatis* are shown in Dr. Gillies's monograph beautifully photographed, and there are an accompanying translation and most useful notes and a glossary. They deal with such questions as the regulation of the health, the quantity of the food, the eating of food, the times of eating, and the age and temperament, and are full of wisdom. The great interest of the book lies in the fact that it shows that away back in the fifteenth and sixteenth centuries there were physicians and scholars in the far north and in the western isles of Scotland who were men of profound practical experience themselves, and who, in addition, had a thorough knowledge of all that was best in the ancient Grecian, Roman, and Arabian medical literature.

Dr. Gillies is to be heartily congratulated on having produced a work which has been to him a labour of love.

What Shall I Eat? By Dr. F. X. GOURAUD, Formerly Chief of the Laboratory of the Medical Faculty of Paris. Translated by FRANCIS J. REBMAN. London and New York: Rebman, Limited. 1911. Pp. 379. Price 6*s.* net.

THIS book is an attempt to tell us what we should eat, drink, and avoid, both in health and disease. Its sub-title is "A Manual of Rational Feeding." There is much that is interesting in the work, but the physician will have to read a little between the lines and be careful not to accept all its dicta. The author mentions in succession each article of food, e.g., meat and its varieties, fish, milk and its products, fats, eggs, cereals and their products, legumes, potatoes, vegetables, fruits, condiments, and what he calls "nerve foods," and winds up with short chapters on beverages and vegetarianism. He mentions the chief characters, composition, and uses of each food, its action on the digestive and other organs, and gives the indications for or against its use in health and disease. We do not think that the translator has been altogether successful in conveying the meaning of the author if we may judge by a few examples. "The nitrogen of beef is composed of albuminoids—i.e., myosin, myostroin" (p. 21); "The extravagant content of nitrogen forms the generation of microbes" (p. 29); "Nitrogen forms a splendid breeding ground for intestinal bacteria"; urea is "the issue of albumin" (p. 33); meat "wears out the parenchyma of the liver"; while brain, we are told, is a "food for rephosphoratisation." Under the head of Juices of Meat we find: "There is a larger number of commercial articles which are prepared in ever so many different ways, the principal advantage of which is simply one of commodity." There are some strange inconsistencies. We are told that "The Japanese live almost exclusively on fish, and but rarely eat meat," and a little later (on p. 177), under the head of "Rice": "We may at once claim that the Russo-Japanese war was the triumph of rice over rye." Fish itself is a "rephosphorating food," while milk is "essentially a living food," and is said to contain "yeasts." What is one to make of the following cryptic sentence? "The habit of finishing every meal with a bit of cheese often enough proves fatal to men of the world" (p. 138). The well-known French word *apéritif* is rendered by the word "aperient"—a very different affair. The translator has added a glossary in which we find "Ternary bodies" defined as "the fats, albumins, and carbohydrates of any food." We cannot agree with the enthusiastic translator's implication that the book deserves a place on the reference book-shelf of every medical man. There is a copious index of the diseases referred to in the text, and a short preface by Professor Armand Gautier of Paris.

Practical Photo-Micrography. By J. EDWIN BARNARD, F.R.M.S., Lecturer in Microscopy, King's College, London. Illustrated with 79 figures in text and 10 plates. London: Edward Arnold. 1911. Pp. 322. Price 15*s.* net.

PHOTO MICROGRAPHY now embraces a wide range of subjects, more especially in histology, bacteriology, and pathology; and in recent years petrology and metallurgy are the latest fields for its application. There is, therefore, ample room for a text-book dealing with this subject, and it is with pleasure that we welcome the excellent treatise of Mr. Barnard. To become expert at the work the operator must master the use of the microscope, and know the optical

principles of its construction as well as the technique of pure photography. To these ends the author devotes several chapters to the general construction of a microscope, its optical equipment—objectives and oculars (emphasising the fact that it is advisable to purchase these only from the makers of highest repute), substage condensers, and illuminating apparatus, second only in importance to the lenses themselves. Illuminants are next dealt with, and the importance of electrical illuminants is pointed out. The various forms of photo-micrographic cameras are described and amply illustrated. Here we would point out the great importance of the use of dark-ground illumination, as, for example, by the use of a parabolic reflector, in instantaneous photography of living bacteria, trypanosomes, and spirochætæ, an art that has recently been applied by Dr. Comandon to cinematography. Chapters follow on the use of the microscope and its several parts, and above all in photography the necessity for preventing vibrations. As in photographing microscopic objects colour screens are almost invariably necessary a full account of their nature and use is given, together with an account of the various photographic plates on the market. The plate having been exposed, the next stage is the development of the negative, which does not differ from the method used in ordinary photography. Some special processes are then described—e.g., how to use ultra-violet rays, photography of metals, of cultures of bacteria, and the production of lantern slides by the three-colour process of Sanger-Shepherd, the autochrome, the "Thames" and Dufay colour processes. There is no coloured plate to show what can be done by these methods. The last chapter is devoted to the description of "some progressive examples" of the ten plates, which include illustrations of sections of stems of plants, of foraminifera, scalp, tongue, medulla oblongata, bacteria, trypanosomes, pus and gonococci (× 1500), yeast, typhoid bacillus, surfaces of metallic alloys, &c. There is a useful appendix, which includes a list of books of reference (exclusively English however); there are no references to French or German publications. The work will prove most useful to all who practise a fascinating art and a most valuable branch of scientific technique.

Diseases of the Skin. By JAMES H. SEQUEIRA, M.D. Lond., Physician to the Skin Department and Lecturer on Dermatology at the London Hospital. With 44 plates in colour and 179 other illustrations. London: J. and A. Churchill. 1911. Pp. 539. Price 25*s.* net.

Dr. Sequeira is to be congratulated on having produced so excellent a text-book on skin diseases. The volume answers all the tests demanded of a satisfactory text-book for students and practitioners. It is clearly written in a simple, restrained style; the descriptions of the various diseases are vivid and systematic; throughout there is abundant evidence of careful selection and pruning. The author has avoided the common error of dealing too lengthily with certain diseases in which he takes a special interest, and dismissing others too abruptly. This cardinal virtue is attained only by teachers of conscientious and methodical habit; and perhaps its presence in this text-book is explained by the first words of Dr. Sequeira's preface: "The book began with notes for a course of lectures delivered in the Skin Clinic at the London Hospital in 1902, and has gradually grown with the experience of nine years' teaching."

The chapters of the book have been arranged as far as possible on etiological lines, but in many instances this has been replaced by a morphological classification, as is usual in the majority of dermatological works. The list of contents and the index overcome most of the difficulties that arise from the classification; but the failure of all classifications to meet practical problems of diagnosis can always be detected by the reader who seeks for it. To mention one example, folliculitis decalvans is described on page 166, under Microbic Affections of the Skin, as an infection of the hair follicles of the scalp, while the not dissimilar condition, Brocq's pseudo-pelade, is described on page 502 under Diseases of the Hair. Cross references in the paragraphs on diagnosis are the only means at present of diminishing these difficulties caused by imperfect knowledge, and hence by imperfect classifications of skin diseases. As an example of Dr. Sequeira's concise brevity in description we refer our readers to his clear *résumé* of the X ray treatment of ringworm, and to his admirable chapter on Seborrhœa. We are glad to see at last in an English text-book a complete, though brief, presentation of Dr. Sabouraud's illuminating researches on the true nature of pityriasis and seborrhœa.

We have rarely seen better coloured plates, which, with a few exceptions, are from the author's own cases, taken by Dr. Arnold Moritz direct in three colours from the patients; and the black and white illustrations are equally good. Among the 179 illustrations, that of molluscum contagiosum is one of the few that fail to give a life-like representation, which in some of the serious cases is positively startling. The value of the book is enhanced by three appendices on mineral waters and spas, on drugs useful for the internal treatment of skin diseases, and on formulæ for local applications of ointments and lotions, baths and powders. There are a number of useful references throughout the book—an uncommon feature that will prove of great value to students who desire to follow up in detail any subject that particularly interests them.

JOURNALS AND MAGAZINES.

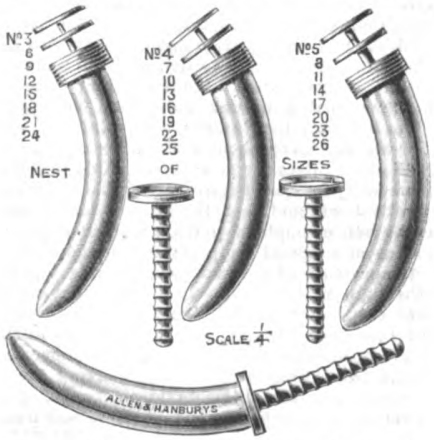
Journal of Pathology and Bacteriology. (Official Organ of the Pathological Society of Great Britain and Ireland.) Vol. XV., No. 4. Published from the Department of Pathology, University of Cambridge. Price 7*s.* 6*d.* Yearly subscription, £1 1*s.*—In observations on animals showing the symptoms of the disease called "distemper," Dr. J. P. McGowan of Edinburgh isolates constantly from the nose, pharynx, and trachea of men, monkeys, ferrets, goats, guinea-pigs, rabbits, and especially from cats and dogs suffering from symptoms resembling those of "distemper," a short Gram-negative, slightly motile, flagellated bacillus, sometimes nearly a coccus, and growing in chains in broth and in the infected tissues; neither involution forms nor spores have been observed. The organism grows well on ordinary media and forms a yellowish-brown thick growth on potato; in media containing dextrose and other carbohydrates and in litmus milk there is a marked production of alkali. The organism grows well without liquefaction on gelatin, and there is no formation of indol. Cultures of the organism were pathogenic to dogs, cats, and other animals on intraperitoneal inoculation, and when applied to the nasal mucous membrane of healthy dogs can set up the clinical symptoms of "distemper." Dr. T. Addis of Edinburgh writes on the Pathogenesis of Hereditary Hæmophilia. As the result of a very careful series of quantitative experiments with solutions of fibrinogen, thrombin, and prothrombin, prepared from normal blood and from the blood of well-marked cases of hæmophilia, and with thrombokinase solutions prepared from human tissues, the author comes to the following conclusions regarding the share which each of these factors has in causing the delayed coagulation of hæmophilic blood. Fibrinogen is present in hæmophilic blood in normal amount and is readily coagulated. The amount and activity of calcium, prothrombin, and thrombokinase, in hæmophilic blood are normal. As regards the thrombin, there is in hæmophilic blood

a marked delay in its formation, though in the end as much is formed as in normal blood. This delay in the formation of thrombin in the shed blood, he maintains, is proportional to the retardation of coagulation, of which it is the cause, and is not due to deficiency of thrombokinase. There is no difference in the amount of antithrombin in normal and hæmophilic bloods. Professor D. A. Welsh of Sydney, in a note on the positive and negative phases of coagulation of blood in man, recalls the observation of Wooldridge, that injection of tissue extracts (thrombokinase) may cause intravascular clotting (positive phase). He holds that these phenomena may be reproduced in man in disease associated with cellular disintegration and leucocytosis. The white fibrin thrombi in the heart and pulmonary artery, which are common in pneumonia and leukæmia, are formed during life and represent the positive phase. They are a cause of death rather than the results of dying. Dr. M. A. Ruffer, of Alexandria, in a paper on arterial lesions found in Egyptian mummies, dating from 1580 B.C. to 525 A.D., records that the lesions of advanced atheroma are common and present the same features, on microscopical examination, as do present-day specimens. Among the suggested causes of atheroma, tobacco and syphilis may certainly be excluded, probably also alcohol, hard muscular work, and an excessive meat diet. Dr. T. R. Elliott of London and Mr. R. G. Armour of Toronto, in a paper on the development of the cortex in the human suprarenal gland and its condition in hemicephaly, maintain that the large size of the human suprarenal gland during fœtal life is due to the presence, between the cortex and medulla, of a mass of tissues which resembles cortex but does not contain any doubly-refracting fatty material. This "fœtal" cortex appears at an early stage and persists till birth. After birth it undergoes fatty change and rapidly degenerates until at the end of the first year it has usually disappeared. It has not been found in animals, and appears to be peculiar to man. It was absent in the small suprarenals of a case of hemicephaly. Professor H. Seidelin, of Merida, Mexico, under the title "Epidermoidal Metaplasia in Ureter and Pelvis of Kidney," records the occurrence of stratified squamous epithelium in the pelvis and ureter, asssociated with numerous small calculi and ulceration. Dr. A. G. Anderson of Aberdeen describes a case of psammo-carcinoma of the pancreas. This was a tumour arising in the head of the pancreas, with a well-marked alveolar structure and showing numerous calcareous nodules made up of concentric layers. These psammoma bodies were present in the neighbouring glands, but not in the metastatic growths in the liver and lung, and arose apparently by degeneration of the carcinoma cells. Dr. Carey Coombs of Bristol, in an article on the microscopic or "submiliary" nodules of active rheumatic carditis, states that active cardiac rheumatism is constantly associated with the presence of small inflammatory foci in the muscle and serous membranes. These foci consist of fibrin, lymphocytes, and characteristic large cells which are often multinucleated. They are not found in other forms of infective carditis, and appear to be characteristic of rheumatic endocarditis and pericarditis. They are most abundant in the left ventricle and are rare in the auricles. In structure they appear to be identical with the subcutaneous rheumatic nodules. Dr. J. O. W. Barratt of Liverpool, in "The Modelling of Mitotic Forms," shows how accurate and instructive models of the chromosomes in dividing cells may be made by making plans of the dividing nucleus in the successive planes formed by using the fine adjustment of the microscope. From these, wax models magnified 12,000 times are prepared and mounted on a wire frame; from these, again, permanent wooden models are constructed. Professor I. Walker Hall of Bristol gives a short account of some valuable observations on the bone marrow of the humerus made by the late Dr. F. F. Leighton, who classified the bone marrow of 63 cases under seven headings according to their naked-eye appearances—appearances which accorded well in almost every case with definite microscopical "findings."

New Inventions.

"NESTED" UTERINE DILATORS.

THE accompanying woodcut well illustrates a new form of uterine dilator which has been made for me by Messrs. Allen and Hanburys, Limited, of 48, Wigmore-street, London, W. The set is so arranged that the smaller sizes telescope into the larger instruments, with the result that when "nested" the 21 dilators form three pieces with accompanying handles. The main objections to all dilators which have hitherto been made on this principle are their great weight and considerable bulk. The present set of "nested" dilators, however, is



eminently portable and comparatively light. In actual practice I find one handle sufficient, since when one size is inserted the handle is detached and rapidly fitted to the next number, and the smaller instrument withdrawn as the larger one is ready to insert. The principle on which the handle is fitted or detached is simple and rapid, and when the handle is adapted for insertion its stability and mechanical advantage are superior to those of the double-ended instrument.

Devonshire-place, W.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Killian of Freiburg, whose name is well known in connexion with bronchoscopy, has been appointed to the chair of Laryngology, in succession to Dr. Fraenkel. Dr. Th. Weil of Charlottenburg, author of many works on hygiene and technology, has been granted the title of Professor.—*Bordeaux:* Dr. Pachon, *agrégé*, has been appointed Professor of Physiology, in succession to Dr. Jolyet.—*Breslau:* Dr. Richard Stumpf of Königsberg has been appointed First Assistant in the Pathological Institute, in succession to Dr. Winkler who goes to Posen. Dr. Hermann Küster has been recognised as *privat-docent* of Midwifery and Gynæcology, and Dr. Karl Fritsch as *privat-docent* of Surgery.—*Cracow:* Dr. Sigismund Radlinsky, Assistant to Professor Kader has been recognised as *privat-docent* of Surgery.—*Erlangen:* Dr. von Liebermann has been recognised as *privat-docent* of Physiology.—*Gratz:* Dr. Karl Potpeschnig has been recognised as *privat-docent* of Children's Diseases.—*Montpellier:* Dr. Vires, *agrégé*, has been appointed Professor of Therapeutics and Materia Medica, in succession to Dr. Hamelin.—*Munich:* Dr. Hugo Kaemmerer has been recognised as *privat-docent* of Medicine.—*Paris:* Dr. Paul Teissier, *agrégé*, has been appointed Professor of Internal Pathology in succession to Dr. Dejerine. Dr. Letulle, *agrégé*, has been appointed to the chair of the History of Medicine and Surgery, in succession to Dr. Chauffard. Dr. Weiss, *agrégé*, has been appointed to the chair of Medical Physics, in succession to Dr. Gariel.

THE

BRITISH MEDICAL ASSOCIATION.

SEVENTY-NINTH ANNUAL MEETING IN BIRMINGHAM.

THE SECTIONS.

MEDICINE.

THURSDAY, JULY 27TH.

President, Dr. A. H. CARTER (Birmingham).

Dr. W. HALE WHITE (London) opened a discussion on

Obscure Cases of Fever without Physical Signs.

He pointed out that as means of investigation became more numerous the cases in which we cannot explain the cause of pyrexia would be fewer. For example, the X rays now helped us to recognise deep seated pus, and an agglutination reaction taught us to detect typhoid fever in those in whom the cause of the pyrexia might formerly have been overlooked. Mouth temperatures might be misleading, since if the patient had been breathing cold air the thermometer would register too low, if there had been much exertion it would register higher than the disease warranted. Bardswell and Chapman had recently shown that a normal individual walking for one hour at four miles an hour raised his rectal temperature to 100·6° F., walking for one hour at six miles an hour he raised it to 103° F. Sometimes the power of the body to maintain its temperature fairly constant irrespective of that of the surrounding air broke down, and then the patient had a sunstroke. This was the best example of pyrexia without physical signs. The influence of external temperature was shown in the fact that the temperature of fevered patients was higher in the hot months than in the cool. It was well known that the majority of cases of rheumatic hyperpyrexia occurred in the months of June, July, August, and September, and Dr. J. H. Bryant had shown that this was also true of most cases of hyperpyrexia from other causes. The younger the patient, the more easily was the thermotaxic mechanism put out of gear; therefore, in infants, the temperature was likely to be raised by very slight causes. Certain chemical bodies were sometimes the cause of pyrexia, and belladonna, cocaine, and β-tetrahydro-naphthylamine were mentioned in illustration. Dr. Hale White referred to some experiments done in conjunction with Dr. J. Fawcett as to the results of injecting the last-named drug into rabbits. In one the temperature rose 9·9° F. The drug probably acted by increasing the production of heat. Excess of carbohydrate food could sometimes lead to pyrexia, and, in illustration, Dr Hale White referred to a case published by Dr. H. Davy,[1] a former President of the Association, who had pointed out that carbohydrate fever must always be thought of in children who have those frequent attacks of pyrexia which were formerly called febricula and are now often erroneously said to be influenza. Fever due to some abnormal body in the intestines might be quite unsuspected until examination of the stools showed the presence of blood and mucus in them. Pyrexia due to disorders of the nervous system was next referred to. Fracture of the spine, especially if in the cervical region, and damage to certain parts of the brain, especially the corpus striatum, would lead to pyrexia. Dr. Hale White described the results of his experiments, showing that damage to the corpus striatum in rabbits produced considerable pyrexia. The importance of the central nervous system in relation to pyrexia was well shown in the study of hyperpyrexia. Dr. J. H. Bryant found hyperpyrexia in 10 out of 258 cases of fractured skull. Dr. Hale White had seen the temperature rise to 107·4° F. in cerebral hæmorrhage, to 107° in cerebral softening, to 108° in cerebral tumour and in delirium tremens, to 108·4° in chorea, and to 109·1° in convulsions. All such cases might be said to be cases of pyrexia without physical signs, and the explanation in all probability was that the disease of the brain had thoroughly upset the thermotaxic mechanism. Cases of hysterical pyrexia were next considered. The possibility of fraud in these cases was mentioned and illustrated by referring to the case of a nurse whose axillary temperature was stated to be 110°, the explanation being that the patient had heated up the axilla by a very hot indiarubber hot-water bottle. Her rectal temperature proved to be normal. Dr. Hale White was of opinion that a survey of published cases showed that some were genuine, and suggested that just as in hysterical paralysis or hysterical convulsions the cerebral motor mechanism had gone mad, so in hysterical pyrexia the cerebral heat mechanism had gone mad. He then gave details of two cases of hysterical pyrexia which he had observed. The importance of the examination of the blood in any case in which the cause of the pyrexia is not obvious was then emphasised. An excess of polymorphonuclear cells would often indicate pus, but was of less clinical value than might be thought, since usually when there was a sufficient increase to confirm the suspicion of pus, this could be detected by other means. Moreover, a considerable quantity of pus might be present without any increase in the number of these cells, and in some diseases such as pneumonia they might be increased without suppuration being present. In some examples of pyrexia—e.g., enteric fever—a leucopenia was present. Sometimes the parasite causing pyrexia could be found in the blood—e.g., in malaria, blackwater fever, sleeping sickness, tick fever, relapsing fever, and filariasis. Again, bacteria might be found in the blood, as in malignant endocarditis. A Wassermann reaction or one of its many modifications might show whether an obscure fever was due to syphilis. The examination of the blood for agglutination reactions helped to a diagnosis in typhoid fever, paratyphoid fever, Malta fever, dysentery due to Shiga's bacillus, and glanders. Dr. Hale White discussed the limitations and fallacies of the agglutination test in enteric fever. He then referred to the estimation of the opsonic index as an aid to diagnosis, more especially when it is suspected that the pyrexia is due to the tubercle bacillus. The cases of obscure fever due to diseases of the blood were then illustrated by reference to pernicious anæmia, Hodgkin's disease, and acute lymphatic leukæmia. The fact that examination of the cerebro-spinal fluid will often yield positive evidence of meningitis before any optic neuritis is discernible was mentioned as of importance in the diagnosis of cases of obscure pyrexia. Dr. Hale White stated that it was probable that the nature of some cases of fever was overlooked when the explanation should be sought in the condition of the urine, which though perfectly free from albumin, blood, and casts might contain streptococci or bacillus coli, to which the fever was due. The most common cases of obscure pyrexia to be cleared up by examination of the urine were those which occurred in pregnancy. Before giving up any case as inexplicable the urine should always be examined bacteriologically. Forgetfulness of the fact that malignant disease may be the cause of pyrexia could lead to mistakes. As a rule the growth was one which was rapidly spreading and of considerable size, or there were many growths throughout the body. Dr. Hale White had several times known a large growth of the liver to be associated with pyrexia for many weeks. Cirrhosis of the liver might be a cause of pyrexia, as was pointed out by Carrington, and a so-called tropical liver might be seen in this country as a cause of fever. Pylephlebitis and inflammation in connexion with the biliary passages must also be remembered as possible causes. Dr. Hale White believed that mistakes were most often made about obscure pyrexia by failing to discover deep-seated pus, especially in that an empyema after pneumonia was regarded as chronic pneumonia or tuberculosis. Pus in connexion with the teeth, the antrum, and the cavities of the nose was often difficult to find, and so also was that of a small subdiaphragmatic abscess. A retro-pharyngeal abscess might be overlooked, and pyrexia after an operation thought to be caused by pneumonia might really be due to suppuration in connexion with the wound. Malignant endocarditis was perhaps the next commonest cause of difficulty, and the pitfalls in the diagnosis of this disease were discussed. Failure to examine the urine bacteriologically was probably the next most common cause of non-success. Next on the list of difficulties Dr. Hale White placed obscure pyrexia due to tuberculosis. He pointed out the importance of repeated examination of the sputum or urine in such cases and discussed the value of X ray examinations and of the tuberculin tests in this connexion. Enteric fever and paratyphoid fever must also not be forgotten.

Sir WILLIAM OSLER (Oxford) divided the causes of pyrexia

[1] THE LANCET, vol. ii., 1904, p. 882.

of obscure causation into three chief groups: (*a*) neurotic, (*b*) infectious, and (*c*) those due to obscure unrecognised tumours. The first group was not a large one. He referred especially to cases in fat children and in young people at puberty. In the second group unrecognised tuberculosis accounted for a good proportion. In latent tubercle there was often slight transient fever without physical signs. Tuberculous glands were not always detectable in children, and might cause fever lasting for weeks. Fever due to chronic septic endocarditis was another example to be included in this group. It might continue for months without observable physical signs, either cardiac or otherwise. A useful hint in regard to these cases was sometimes given by the appearance of ephemeral nodes on the fingers and toes like an urticarial wheal. Syphilis was also sometimes associated with fever of obscure origin. Gummata in the liver were often present in such cases. Colon bacillary infections of the urinary tract were then referred to, and their characters were outlined. Such conditions were common in pregnancy and during childhood. Vaccine treatment of these cases in his experience had not been very successful. In the tumour group of causes he referred to cases of Hodgkin's disease and to latent obscure sarcoma of the retroperitoneal tissues and liver.

Mr. E. C. HORT (London), after outlining his views as to the genesis of fever and to the doctrine of the unity of fever, which is based on the observation that in man fever follows cell destruction, proceeded to classify cases of fever under three headings: (1) Those cases due to absorption of foreign products; (2) those due to absorption of native products; and (3) unclassed fevers, a group which contains very few cases, such as the fever due to hysteria. In endeavouring to elucidate the cause of fever it was therefore necessary to eliminate one by one all possible causes of cell destruction, including the infections. He illustrated his remarks by a diagram and gave a table classifying fevers on the principles outlined.

Dr. E. HOBHOUSE (Brighton) in his remarks described a physiological fever in children due simply to ordinary metabolism being hastened. It was desirable to make prolonged observations in children. He believed that fever in syphilis was commoner than Dr. Hale White suggested, and it could occur in tertiary and hereditary conditions Cirrhosis of the liver might also cause disturbance of temperature. He also referred to latent tuberculosis, erythema nodosum, and bacilluria in children. He had not found vaccines successful in his experience of the last-named condition. Some cases of fever were not even explained after post-mortem examination.

Dr. W. J. TYSON (Folkestone) emphasised the importance of sex and age in regard to the question under discussion, conditions which he thought had not received sufficient notice by previous speakers. The temperature in the female was, as a rule, higher in disease than that of the male, perhaps by a half to one degree. In children the temperature was considerably higher than in the adult and was raised by comparatively slight means. He alluded to the effects of indigestion of various kinds of food in children.

Dr. C. A. HAWTHORNE (London) said he thought the field of pyrexia had been so thoroughly explored in the discussion that it would be difficult to imagine "unexplained pyrexia" as an appropriate subject for the Section to consider for many years to come. One more precaution might be added to those mentioned by Dr. Hale White—namely, the necessity for the use of a thermometer of guaranteed accuracy; this, of course, applied to subfebrile rather than to severe febrile temperatures. He put in a plea for the recognition of rheumatism as among the possible causes of pyrexia occurring apart from physical signs or other objective evidences of local disease. No doubt in many cases of rheumatic fever there was so close a correspondence between the extent and severity of the polyarthritis, on the one hand, and the height of the temperature record, on the other, that it was common to accept the view that the relationship between the two was that of cause and effect. But manifestly it was quite consistent with the facts to hold that both events, the pyrexia and the arthritis, were results of a common cause, and if this were granted it must be recognised that theoretically at all events the one might occur apart from the other. Further, it was noteworthy that unexplained pyrexia was more common in children than in adults, and especially in "neurotic" children. But it was in children particularly that rheumatism tended to assume a non-articular form, and children with a rheumatic inheritance were prone to be "neurotic." It seemed possible, therefore, that fever might, at least in children, sometimes be the sole evidence of rheumatism.

Dr. T. STACEY WILSON (Birmingham) was of opinion that rheumatism was not essentially a joint disease. Certain organisms found their final nidus in the tissues and fluids of joints where the alkalinity of the fluids was lessened. The effect of the salicylates in removing this condition might account for their efficacy in rheumatism. He also mentioned rat-bite fever and gastric ulcer as examples of obscure pyrexia.

Dr. R. D. RUDOLF (Toronto) drew attention to the question of the level of the normal temperature when taken in the ordinary way and referred to the statement of Wunderlich that the normal levels lay between 97·2° and 98 8°. In some observations upon a number of students Dr. Rudolf had found that the average temperature in the morning was 97·4° and in the evening 97·6°.

Dr. C. H. MELLAND (Manchester) expressed his desire merely to underline a few of the points which Dr. Hale White had dealt with in his very exhaustive paper. It was a very common error to diagnose malaria in any obscure case of fever if the patient *at any time of his life* had ever had malaria or lived in a malarial country. Acute leucocythæmia was another cause of obscure fever which he believed to be more common that was usually recognised. It sometimes occurred without any enlargement of lymphatic glands or of spleen to draw attention to it, and though an examination of the blood should demonstrate the nature of the fever it was not uncommonly omitted. And, indeed, in some cases, though it might sound paradoxical, there was no increase in the number of leucocytes, at any rate until the very last stage of the disease. With regard to ulcerative endocarditis, Dr. Melland suggested that during the last ten years this disease had to a large extent changed in type. Instead of being an acute disease running its course to a fatal ending in a few weeks and with well-marked signs of cardiac trouble, it had become a very chronic febrile affection, lasting many weeks or months, with constant or recurrent periods of infection, but often with very few symptoms or physical signs to draw attention to the heart.

Dr. WILLIAM HUNTER (London) would distinguish between the disease and the fever accompanying it. He divided the causes of fever into two main groups: (1) the non-infective and (2) the infective, the latter group being subdivided into specific and non-specific. Any part of the alimentary tract might become the source of infection.

Dr. HALE WHITE replied.

SURGERY.

THURSDAY, JULY 27TH.

President, Sir THOMAS F. CHAVASSE (Birmingham).

Mr. H. ALEXIS THOMSON (Edinburgh) opened a discussion on

The Technique of Wound Treatment.

He commenced by saying that surgeons are all agreed that it is essential to exclude micro-organisms from wounds, but the methods to be employed are still open to discussion. Different surgeons showed more uniformity in the results they obtain than might have been expected from the diversity of methods. The thorough carrying out of any method and the personal factor are of the chief importance. There is no such thing as an aseptic method; it is the result which should be aseptic. In comparing different methods it is very desirable that we should trust not to general impressions but to exact statistics of large numbers of cases. As to the means of sterilisation, they are more often wanting in efficacy than is usually thought. Even when sterilisation of dressings by heat is employed, it is desirable to employ one of the capsules devised for the purpose, which can show that the temperature in the middle of the dressing has been sufficiently high. If sepsis should occur during the operation, it is necessary either to return the instruments to the steriliser or to keep them in an antiseptic solution. For the sterilisation of catgut we have better methods than formerly, but it must not be forgotten that iodised catgut causes more exudation from the tissue than does simple catgut, and drainage may be needed. It is a good test of the thoroughness of a

surgeon's method if he can employ buried silk. As to the hands, there is a large consensus of opinion in favour of dehydration by alcohol, but it is very important that the surgeon should never allow his hands to become septic. The wearing of gloves is a personal matter; and it must not be forgotten that surgeons can obtain unsurpassed results without gloves. If a surgeon never uses gloves he must get his hands infected sometimes, while if he uses gloves only occasionally, as in septic cases, he will find them a great handicap. Some surgeons may be more dangerous with gloves than without them. It must be remembered that the use of gloves does not remove the necessity for the sterilisation of the hands. With regard to the skin of the patient, dehydration by alcohol is the most satisfactory method, and it acts not by killing the germs but by fixing them on the skin and so nullifying their action. The results of the use of alcohol are equal to those of any other method. The use of iodine for preparing the skin of the patient has at present a great popularity, but if it is employed it is essential that the skin should not be washed just before. Iodine is a more reliable steriliser of the skin than is alcohol alone, though Kocher does not think so. For children the iodine should be used of less strength than for adults, and it should be applied only before the operation, as its excessive use may cause eczema. In adults the iodine should be employed both before and after the operation.

Mr. HERBERT J. PATERSON (London) claimed that for the sterilisation of instruments all surgeons agree as to the value of boiling. During the operation it is better that the instruments should lie in an antiseptic solution, for if they lie in sterile water the water is almost always septic within ten minutes. If catgut is to be properly sterilised it must not be allowed to come in contact with water before it is prepared. Gloves should be sterilised dry, for if they are put on wet the hands are always septic by the end of the operation, and if a puncture of the glove should occur it may cause contamination. For sterilisation of the patient's skin a solution of iodine is the most satisfactory. The best test of the sterile nature of the skin is its condition at the end of the operation and not at the beginning. Out of 22 cases treated with iodine solution only one showed signs of sepsis at the end of the operation.

Mr. G. P. NEWBOLT (Liverpool) considered that the use of gloves became natural to a surgeon after a little use; and he employs them always, except for enucleation of the prostate. He has noticed that those surgeons who do not wear gloves employ drainage more than those who do wear gloves. He considered it to be a mistake to operate, except in an emergency, on a patient the day after admission to the hospital, especially when the operation is on the mouth or rectum, where much preliminary cleansing is advisable. He always performs a preliminary tracheotomy in mouth cases, and he never has septic pneumonia. In painting the patient's skin he uses equal parts of the liniment and tincture of iodine, and he is satisfied with the results. As to whether the skin is really aseptic or not he does not care, as it is of no practical importance. He has met with two cases of post-operative tetanus, but he was unable to find any cause. In the sterilisation of the knife boiling in oil gives good results, but it is an expensive method.

Mr. C. A. LEEDHAM GREEN (Birmingham) contributed to the discussion by reading a paper on

An Inquiry into the Value of Sterilisation of the Skin by Iodine.

Little experimental work has been done to test the claims which have been made for iodine as a steriliser of the skin. In estimating the value of any antiseptic it is essential that the antiseptic be neutralised before any attempt at culture be made. Cultural experiments were made with small portions of ligature silk and glass beads infected with various organisms. Alcohol of 70 per cent. strength has more antiseptic power than alcohol of any other strength. Tincture of iodine proved to have the greatest bactericidal power when prepared with 70 per cent. alcohol, and experiment showed that this is not due, as Kutscher claims, entirely to the alcohol, the iodine being a superfluous ingredient. Comparative tests with tincture of iodine (70 per cent. spirit), plain alcohol (70 per cent.), and a watery solution of iodine of the same strength showed that whilst the watery solution of iodine possesses decided germicidal properties, it was less potent than the 70 per cent. alcohol, which in its turn was inferior to the tincture, and this was true even with resistant microbes. Further, it was shown that an alcoholic solution of perchloride of mercury of 1 in 1000 of 70 per cent. alcohol was superior in bactericidal power to the tincture of iodine. Experiments were also made upon the skin, and it was proved that the ordinary preliminary washing of the skin with soap and water is not merely unnecessary but actually harmful; for it does not materially lessen the number of microbes, and by macerating the epidermis it hinders the penetration of the iodine or other alcoholic solution. The question was then examined whether iodine has an exceptional power of penetrating and hardening the epidermis. The penetration is not greater than with other alcoholic solutions of a like strength and the hardening of the epithelium is lost in the presence of blood or albuminous fluids. The alcohol is the chief factor in the hardening, and this hardening is of little value except in short operations. Comparative practical tests on the skin with plain alcohol, tincture of iodine, and sublimate alcohol showed the marked superiority of the two last named, which proved to be powerful skin disinfectants, even after special contamination. A true sterility was never obtained, but both methods always greatly reduced the infectivity of the area. Neither of the two methods can be said in any way to guarantee sterility, for the skin which had proved to be practically sterile directly after the process of disinfection gradually became more and more infective as under the imbibition of fluid the hardened epithelium became loosened. Sublimate alcohol has given the better results, there was a slight superiority even when it was merely painted on the skin, but when it was freely rubbed on, as in the usual method of alcohol disinfection, the superiority was much more marked.

Professor C. F. A. KOCH (Groningen) expressed himself on the whole in agreement with those who had spoken. For two years he used tincture of iodine with good results, but the skin was not aseptic. Very good results in accidental wounds and in compound fractures were obtained by the application of balsam of Peru; the wound may do well even when the skin is very septic; the balsam is simply poured into the wound and it heals up without any real sepsis. He considered it a point of importance that wounds should not be dressed too often. He does not use gloves and yet he does not find it necessary to drain more than those who wear gloves.

Mr. T. S. ELLIS (Gloucester) dealt with the treatment of wounds as wounds. He described a case of very severe burn of the neck and ear, which he had treated by daily pulling of the skin at the lower part of the wound in a direction up and out. When the wound had healed the lower part of the scar was soft and non-adherent, while the untouched upper portion of the scar was firmly fixed and heaped up with keloid. Every amputation stump should be persistently moved to keep the skin supple. Sheet rubber with a rough surface on both sides made the movement of the skin easy and painless.

Mr. C. W. CATHCART (Edinburgh) has the patient prepared the night before the operation. The skin is washed, shaved, and dehydrated with alcohol. In his operations he employs what is often called old-fashioned Listerism. The biological effect of iodine on the skin has not been studied. It can be seen that the skin is abnormally vascular, and it is a question whether the effect is not due to the hyperæmia. For the preparation of catgut, he steeps it in a solution of iodine, made by dissolving one part of iodine in 15 parts of proof spirit; and the catgut so prepared is excellent, it does not rot, and it does not cause an undue amount of effusion. For granulating wounds dry dressings are not good, and packing a sinus every day does definite harm.

Dr. J. M. ELDER (Montreal) employs iodine sterilisation of the skin. It produces hyperæmia, and the hyperæmia is the real agent in producing asepsis. The increased supply of blood is not only in the skin itself, but also in the subcutaneous tissue. Balsam of Peru also gives rise to hyperæmia in wounds.

Mr. CUTHBERT S. WALLACE (London) pointed out that any method proposed must be judged by the results. In his practice the skin of the patient is well washed, the surgeon's hands are washed with soap and water, and then dry sterilised gloves are put on. The instruments are boiled and

put on a plain dry cloth, and if they are soiled during the operation they are dipped in sterilised water. As to the results he had obtained, in the last 600 "clean" cases he had only 4 per cent. in which any suppuration occurred.

Colonel HENRY SMITH, I.M.S., said that in the tropics it was necessary to have plenty of air, and therefore dust was very liable to be deposited on the wound and on the instruments. Therefore the instruments were kept in a solution of carbolic and the wound was flushed out at intervals with a solution of perchloride of mercury (1 in 2000). He uses no sponges and seldom drains the wound. Tetanus is one of the most serious complications of a wound, and it is specially liable to follow an operation for hernia. It may also follow an injection of quinine. The explanation is that whenever there is an anaerobic area tetanus bacilli from the blood will settle in it. The ligating of the stump of the sac produces an anaerobic area and the injection of the quinine has a similar effect. The solution of the difficulty is found in not tying but in suturing the sac of the hernia. It must be remembered that in India 50 per cent. of the men have tetanus bacilli in the blood. He uses catgut whenever he can. Want of dexterity has a very definite relation to sepsis, and he believes that all who aspire to success in surgery should have practice in hand work. He thought that not sufficient attention had been given to the after-effects of chloroform.

Mr. DOUGLAS DREW (London) said that as it was impossible to sterilise the skin, and as the skin was always septic at the end of an operation, it is necessary to protect the wound from the skin, and this can be done by clipping thick layers of gauze to the edges of the skin. In clean wounds he uses linen thread for sutures, but in septic wounds he uses catgut, though it is a little liable to give way. Drainage of a wound is unnecessary if the cavity in the wound can be completely obliterated.

Professor I. H. CAMERON (Toronto) declared himself an antiseptic surgeon. The use of iodine previous to operations is confined to emergency operations and to out-patient work. To prepare the skin of the patient it is merely washed with soap and water, while the instruments are sterilised in 1 in 20 carbolic and are then kept in 1 in 60. The dressing consists of gauze wrung out of a solution of carbolic acid in glycerine. As to the results in clean cases there is suppuration in less than 4 per cent. He rubs his hands with mustard and water and he has a high opinion of it. He employs ordinary marine sponges wrung out of 1 in 20 carbolic. He mentioned that he was the only surgeon who did not wear gloves at the hospital to which he was attached, and he claimed that his results were as good as the results of his colleagues. Dexterity in operating was merely a question of practice.

The PRESIDENT confessed that in most respects he followed the teaching of his teacher Lord Lister. He has used gloves for the last eight years, and the results were better than previously. He never uses a mask except when he suffers from nasal catarrh. In operations the surgeon has merely to follow out the precepts laid down by Lord Lister, "Be clean and be careful."

Radium in the Treatment of Malignant Disease.

Dr. RYERSON (Toronto) described two cases of malignant disease which had been treated successfully by Dr. Wickham of Paris. In the first case a tumour appeared in the toe, and after the toe was removed it returned in the foot. Half the foot was amputated and then it appeared in the glands of Scarpa's triangle. Radium was applied and the tumour rapidly disappeared, but it reappeared in the foot, but here also radium caused the tumour to disappear. In the second case a sarcoma appeared in the muscles of the thigh, and after removal it recurred, but the application of radium was soon followed by the disappearance of the tumour. He considered that radium should be used both before and after an operation.

ANATOMY AND PHYSIOLOGY.

THURSDAY, JULY 27TH.

President, Professor THOMAS H. BRYCE (Glasgow).

The PRESIDENT in his opening speech welcomed the visitors, and expressed his deep regret at the absence, through ill-health, of Professor Peter Thompson of Birmingham. He expressed his pleasure that anatomists and physiologists were sitting in joint session, for the modern specialisation of their subjects along somewhat divergent lines had led to serious inconveniences, and a meeting on common ground was necessary at times to bring the two branches of study into harmony. Nothing but good could come from such a union, and it was possible that with proper coöperation a great deal of simplification could be brought about, with a corresponding reduction of the detail of teaching and curtailment of the already overburdened curriculum. As an example of the changes that might be brought about by harmonious working with the physiologist, the President alluded to the study of histology. Physiology of to-day had so many ramifications that the teaching of histology by physiologists was something of a burden, and the growing importance of embryology and of microscopic detail to the anatomist made the teaching of histology almost imperative in his department. The study of microscopic and macroscopic anatomy should now go hand-in-hand, for no anatomist could be equipped properly for any research work unless he be both an anatomist and a histologist. Professor Bryce echoed the sentiments of modern anatomy when he noted that every year brought the work of the anatomist more within the domain of the physiologist, and expressed his conviction that it was by the combined attack of the sister sciences that the great outstanding problems of the human economy were to be solved. It was by such conjoined meetings as these that the truths of vital importance to medical science were to be solved.

Dr. ALEXANDER HAIG (London) then read a paper entitled

Some Factors of the Circulation, admitting of Easy Measurement.

The factors studied were the capillary reflux, the blood pressure, the relation of these two to each other, the cardiac area, and the liver dulness. Dr. Haig dwelt especially upon the capillary reflux as a valuable clinical sign, and he demonstrated his instrument for estimating and comparing it. He discussed the well-known physiological principles which underlay this very ancient method of investigation of the circulation, and he departed from the generally accepted teaching only in regarding the varying amount of uric acid in the blood as responsible for the variations of the reflux.

Professor E. M. WACE CARLIER (Birmingham) and Professor RICHARD ANDERSON (Galway) joined in the discussion which followed Dr. Haig's paper.

Mr. D. P. D. WILKIE (Edinburgh) delivered a paper on, and gave an excellent demonstration of,

The Existence of Valves in the Gastric Veins of Man,

and he extended the scope of his work so as to include other tributaries of the portal venous system. The author commented on the strange fact that although the presence of valves had been noted from time to time in the history of anatomy, still the text-books almost unanimously adhered to the statement that the portal tributaries were valveless. These valves may be demonstrated by the arrest of injections, as Hochstetter first showed, or by pressing their contained blood, as demonstrated by the present author. The valves are more conspicuous and more competent in young children than in adults, and Mr. Wilkie found them present in 38 out of 40 stillborn infants and in some 60 per cent. of 50 adults examined. They are most numerous at the site of the junction of the omental tributaries of the epiploic veins, but they were also demonstrated on other branches of the gastric veins and on the veins of the large intestine. So far the author had been unable to demonstrate them on any of the veins of the small intestine. In lower animals, such as the cat and the dog, these valves are also present. Some very beautiful micro-photographic slides were shown, in one case illustrating competent valves in a woman of 50. The valves appeared to be bicuspid and their structure very delicate.

The PRESIDENT, Mr. J. E. S. FRAZER (London), Professor CARLIER and Professor ANDERSON joined in the discussion.

Dr. A. MACLENNAN (Glasgow) delivered a paper dealing with

The Action of the Ilio-psoas Muscle.

He reviewed in detail the statements from various authors concerning the movements brought about by contraction of the muscle, the general consensus of opinion in text-books being that an abduction and an outward rotation of the femur were produced. From a series of observations on the action of the muscle in women who had recently been delivered, and on whom examination was easy, Dr. MacLennan concluded that

the muscle produced an inward and not an outward rotation of the femur. This conclusion was strengthened by an anatomical investigation into the relations of the muscle to the bone. The author's findings were that the muscle produced (1) abduction, (2) inward rotation, and (3) flexion of the femur on the pelvis.

A general agreement with the author was expressed in the discussion which followed, and Mr. FRAZER drew attention to the precise attachment of the muscle to the lesser trochanter of the femur.

Dr. S. LEWIS GRAHAM (Birmingham) showed a very remarkable Skeleton obtained from a dissecting-room subject at Birmingham University some four years ago. The skeleton was that of a male, the subject of achondroplasia, whose age was 46 years, and whose total height was 4 feet 6 inches. The outstanding characters of this skeleton were noted and demonstrated, and the pathology of the underlying process and its relation to other well-known bony anomalies were discussed.—Much interest was aroused by this very curious set of bones, and in the discussion which followed Dr. DOUGLAS E. DERRY (London) mentioned a case which had recently come under his notice from an ancient Egyptian graveyard.—Dr. GRAHAM, in reply, instanced the wonderfully accurate representations which the Egyptians had left us of what were without doubt examples of achondroplastic dwarfs.

Professor ANDERSON read a paper entitled

On Variation with Special Reference to Muscle.

The author dealt with such subjects as the regenerated limbs of arthropods, and the adaptation of the individual bones in the carpus and tarsus of the elephant. The underlying laws of variation were considered, and a review was made of the various theories put forward. The variations of the human carpus and tarsus were considered, such outstanding anomalies as the os trigonum being discussed. The paper was an abstruse one, not admitting of brief summary, and it was not followed by any discussion.

Demonstration on Reconstruction Models of Ferret's Brain and Pharynx.

Miss RADFORD (Birmingham) exhibited her reconstructed models of the Brain and Pharynx of a Ferret Embryo. The embryo used for this study was 6 millimetres in total length and of a probable age of 19 days. Some 400 sections were made of the head region, and these were reconstructed with a magnification of 100. Three models were shown—one of the head, one of the brain, and one of the side of the neck and the pharynx. A demonstration of the leading points of these models was given, and many of the features displayed were of great embryological interest. Miss Radford received the congratulations of the meeting on her models, but no detailed discussion of the many points of interest raised by them was possible within the time limits of the session.

Dr. J. P. GOOD (Birmingham) showed two reconstructed models of the Head End of a Ferret Embryo of 8 millimetres. This embryo, which was one of the series got together by Professor Arthur Robinson, showed the presence of spina bifida, and the reconstructions were therefore of obvious interest in connexion with a very early stage in the development of this anomaly. Some 360 sections were cut, and two models were reconstructed with a magnification of 50. The more important normal anatomical features of these models were demonstrated, and special attention was called to the sites of the cranial flexures. It appeared that the development of the spina bifida had taken place at the site of an abnormal flexure, and Dr. Good suggested that the flexure was the cause of the development of the spina bifida, but what accounted for the production of this abnormal flexure he was unable to say.

In the discussion which followed, the PRESIDENT alluded to the interest of the association of an abnormal flexure with the production of a spina bifida, and he instanced those cases where an abnormal retroflexion of the embryo in the sacral region is associated with sacral spina bifida.

Mr. FRAZER and Professor ANDERSON also joined in the discussion.

Professor CARLIER read a paper entitled

Notes on Some Effects of Iso-osmotic Solutions of Certain Salts on Frog's Muscle.

The first part of the paper was concerned with the method of experiment and the description of the apparatus devised for studying the behaviour of frogs' muscles when immersed in iso-osmotic solutions of salts. The muscle under investigation was first stimulated in its undrugged condition and a record was taken of its contraction; 20 c.c. of the iso-osmotic solution was then poured into the specially constructed vessel in which the preparation was suspended, and fresh records were taken of its contraction on stimulation. Single break shocks were used in all cases for stimulation, and time records of the immersion were made. Some very beautiful tracings were handed to the meeting illustrating the effects produced, and elaborate tables were constructed to show the behaviour of the solutions employed. All solutions were found to produce some well-marked effect on the muscle, some solutions causing it to shorten markedly and some producing elongation. It was found that the sodium halogens of Group VII. followed the periodic law in all effects, their action becoming more marked with the increasing atomic weight; that the chlorides of Groups I. and II. did not follow the periodic law, or followed it in some effects only.

In the discussion which followed Dr. D. FRASER HARRIS (Birmingham) alluded to the importance of the method as a means of studying the effects of various solutions upon tissues.

Method of Strengthening Wax Plates.—Reconstructed Model of Ferret Embryo.

Dr. THOMAS YEATES (Birmingham) gave two demonstrations, of which the first was directed to call attention to some improvements in the method of strengthening the wax plates used for reconstruction models. Dr. Yeates showed specimens of all the plates used at the present day, as well as of the special type of plate with which he had been working recently. He criticised the various methods which had been employed to strengthen the wax plate, and enumerated the substances which had been used, and with which he had experimented. After trial of many substances Dr. Yeates had obtained the best results from the incorporation of thin sheets of celluloid within the plate. Such plates can be readily handled and possess the advantage that they may be bent without cracking. The samples handed to the meeting met with general approval. Dr. Yeates's second demonstration was on a series of reconstruction models of a ferret embryo of a maximum possible age of 15 days. The embryo was cut in utero, and it showed a remarkable number of points of interest and novelty in connexion with the early stages of the union of the embryo and the uterine wall.—The amount of detail demonstrated by Dr. Yeates baffled any minute discussion, but the PRESIDENT and Mr. FRAZER raised some additional points of interest which the models made clear.

DISEASES OF CHILDREN.

THURSDAY, JULY 27TH.

President, Dr. OTTO J. KAUFFMANN (Birmingham).

Dr. SAMUEL WEST (London) opened a discussion on

The Diagnosis and Treatment of Chronic Pulmonary Affections of Children.

He said that tuberculous pulmonary affections in children were for the most part acute, appearing as acute miliary tuberculosis and acute caseating pneumonia. The chronic lesions indicated by the term phthisis were very rare before the age of five years, and the same remark applied to hæmoptysis. Chronic tuberculous pleurisy was rare compared with the frequency of chronic tuberculous peritonitis, which was remarkable considering the close connexion between the two serous membranes and the very thin partition between them. Tuberculous enlargement of the bronchial and mediastinal glands was a condition of great interest and importance, though they rarely led to pulmonary lesions, unless they perforated a bronchus and set up acute aspiration broncho-pneumonia. In many cases wrongly diagnosed and treated as asthma the symptoms were in reality due to pressure on the trachea by these enlarged glands. Dr. West related an interesting case in illustration. There were several different kinds of emphysema common in childhood, including interstitial emphysema and the transitory over-distension of the lung which resulted from violent coughing, as in whooping-cough, and the collateral emphysema which developed round the patches of collapse in broncho-pneumonia, which often appeared and disappeared

in a remarkable way. True large-lunged emphysema as it occurred in the adult was rare in the child. Collapse of the lung was one of the most interesting conditions met with in childhood, as it was one of the commonest complications of bronchitis and broncho-pneumonia. It was largely due to feeble muscular power and to the want of rigidity of the chest walls. Bronchiectasis in the chronic form was associated with fibrosis of the lung. The peculiar condition described as "turtle lung" was often preceded by a febrile attack resembling pneumonia, to which it was referred, but intercurrent febrile attacks were common enough in bronchiectasis. The treatment of the chronic pulmonary affections of childhood must be on the same general lines as in the adult.

Dr. H. VOGT (Strasburg) said that it was a well-known clinical fact that certain cases of broncho-pneumonia, especially those due to measles and whooping-cough, had a special tendency to run a prolonged course, and that the symptoms were very liable to recur after the disease had apparently subsided. Each new attack brought with it danger, which was greater the oftener it was repeated. The position of predilection of the disease was the left lower lobe posteriorly and laterally. He believed that the pulmonary diseases caused by the influenza bacillus showed a more marked tendency to chronicity than any others.

Dr. J. E. H. SAWYER (Birmingham) laid stress upon the extreme rarity of chronic tuberculosis of the lungs in children, more especially on account of the misleading reports of school inspectors, in which this affection was diagnosed in from 3 to 60 per 1000 of all children treated. In his examination of 10,000 children he had only diagnosed phthisis of the adult type in 11 cases.

Dr. W. R. JORDAN (Birmingham) agreed with Dr. Sawyer's remarks, and drew attention to the importance of the pharynx and naso-pharynx in the production of the frequent coughs of childhood.

Dr. D. BARTY KING (London) thought that pulmonary tuberculosis occurred in from 3 to 5 per 1000 in London school children aged from 8 to 12, and that latent tuberculosis existed somewhere in many others.

Dr. N. C. HARING (Manchester) recommended swabbing of the larynx or trachea in these cases as a means of obtaining tubercle-laden mucus when cough and sputum were absent.

Professor STOELTZNER (Halle) advocated the use of fibrolysin in the chronic fibrotic pulmonary diseases of children.

Dr. D. STANLEY (Birmingham) considered that a number of the cases of so-called "chronic bronchitis" in children were due to a chronic adenoid hypertrophy, not in the pharynx so much as in the larynx and bronchi. These, he believed, were the patients so often wrongly diagnosed as tuberculous.

Dr. C. P. LAPAGE (Manchester) considered that phthisis was not very rare in children, especially in older children. Probably the bronchial glands were often the seat of primary infection, and the disease spread from them to the lungs.

Dr. ELIZABETH J. MOFFETT (Stafford) said that in examining school children some 15 to 20 per cent. were found with impaired notes on percussion either at the apices or bases, or both. She believed that many of these children developed phthisis later, but many cases cleared up when adenoids were removed.

Dr. W. EWART (London) agreed with Dr. Moffett's conclusion that local impairment of the percussion note was not always due to tuberculosis, but was in children frequently the late result of rickets, which caused imperfect expansion of parts of the thorax. In the treatment of bronchiectasis he recommended the systematic use of the "infant exerciser" which he had devised, which acted by emptying the sacculations and expanding the lung.

Dr. A. E. NAISH (Sheffield) agreed that chronic tuberculosis in children of school age was uncommon, though enlarged mediastinal glands were fairly frequent.

Dr. E. C. MYOTT (Newcastle) held that the majority of children who suffered from chronic cough without physical signs were mouth-breathers.

Dr. WEST replied to the remarks of the various speakers.

Dr. VOGT read a paper on

Disturbances Arising from Milk Feeding in Children after the First Year.

He thought it was not generally known that overfeeding with milk might be injurious to infants, even though the milk was uncontaminated by micro-organisms and irreproachable in quality. There was a definite group of children who were specially liable to disease from overfeeding with milk—namely, those who suffered from the constitutional abnormality described by Professor Czerny under the name of "exudative diathesis." This continued for some time even during later childhood. In this condition there was a pronounced susceptibility of the skin and mucous membranes of the body, resulting in different forms of eczema, as well as catarrhal affections of the respiratory and digestive organs. In these cases milk diet should be greatly restricted, and during the second year small quantities of finely minced meat should be given instead of milk. It was generally supposed that breast-fed infants were protected against rickets, but in his opinion this was a mistake, as children who inherited a disposition to rickets might suffer severely even though fed on breast milk. He also believed that children who had excessive milk feeding were more susceptible to infection than normal children. A third group of diseases directly affected by milk diet was the group of anæmias. Children fed on an exclusively milk diet up to the end of the first year, and even during the second year or longer, almost invariably showed a pronounced pallor. There was a diminution of red corpuscles and of hæmoglobin, but usually no increase of white cells. In these cases it was necessary to diminish the amount of milk and replace it by vegetable food and meat. Constipation also was caused by an excessive milk diet. In conclusion, Dr. Vogt maintained that the long retained dogmatical belief of the medical profession that milk was not only the ideal food for infants, but for every age and every ailment must be abandoned.

Dr. EWART referred to the value of whey as a temporary measure of dieting in infantile milk dyspepsia.

Dr. STOELTZNER quite agreed with Dr. Vogt about the clinical facts and the treatment in these cases.

Dr. R. B. MCVITTIE (Dublin) agreed as to the dangers of excessive quantities of milk, but thought that much of the evils were due to chemical and physiological changes produced by excessive heat in pasteurisation.

Dr. VOGT, in reply, said that he had found no difference between sterilised and unsterilised milk in the feeding of infants and children.

Mr. D. C. L. FITZWILLIAMS (London) read a paper on

Nervous Influence in the Causation of Angeiomata,

based upon notes of 700 cases which he had himself observed. His conclusions from his investigations were: (1) that females were affected more frequently than males; (2) that nævi were almost always present at birth and only comparatively few appeared at a later date, spider marks and deeply seated nævi being the chief exceptions to this rule; (3) that nævi most usually started on the surface and less frequently in the deeper structures; and (4) that their extension and growth were intimately connected with the nerve-supply of the part affected.

ELECTROTHERAPEUTICS AND RADIOLOGY.

THURSDAY, JULY 27TH.

President, Dr. HUGH WALSHAM (London).

The proceedings opened with a paper by Sir VICTOR HORSLEY (London) and Dr. N. S. FINZI (London) on

The Action of Filtered Radium Rays Applied Directly to the Brain,

which was read by Dr. Finzi. The following is an abstract. In the literature on the action of radium rays on the brain Danysz's was the first communication and Obersteiner's and Alquier and Faure-Beaulieu's the most important work. Except for an experiment of Danysz, in which the tube was laid outside the bony canal of the spinal column, these all used external applications, most used toxic doses, and Alquier and Faure-Beaulieu, the only ones who used filters, only employed 1/10th and 2/10th mm. of lead. In the present experiments a platinum tube ½ mm. thick containing radium carbonate, having, according to Rutherford's standard, a content of 27·7 mg. of metallic radium, was used, and was by means of a trephining operation laid directly on the pia mater over the pre- and post-central gyri of three monkeys. In the third monkey a tube containing nearly double the amount of radium was placed on the opposite side, and at a subsequent experiment on the occipital lobe. The time the tubes were left on varied from

2½ to 4 hours, and the animals were killed at periods of 16, 26, 31, and 45 days after the experiments. In none of the animals was the slightest symptom exhibited even where large overdoses had been given. Histologically it was found that the meninges were infiltrated with blood, and that their vessels showed considerable proliferation of the endothelium which sometimes practically occluded the lumen. There was also a considerable formation of fibrous tissue which extended into the cortex and along the sulci. Small hæmorrhages were seen mostly in the first two layers, but in one animal extending as deeply as the fifth layer of the cortex, and it is noted that they are due to erythrocytes which have passed into the perivascular lymphatics and sometimes breaking through these into the surrounding neuroglia. There also occurred in the animal killed on the twenty-sixth day small collections of leucocytes at rare intervals in the first two layers of the cortex. Further, there occurred wedge-shaped thrombotic areas about a quarter of its depth in the cortex. The only change discovered in the nerve cells apart from these thrombotic areas was a condition of hyperchromatosis in the cells of the region of the cortex in which the hæmorrhages occurred. Examined by the Marchi method, there was some degeneration of the pyramidal fibres as well as some fibres in the brain proceeding from the hæmorrhagic areas.

Professor FARR (New Zealand) gave the results of some observations made on the effect of radio-active water on the development of fish. A large amount of the water used in New Zealand came from artesian wells, and it was observed in the hatcheries that ova placed close to the opening of one of the wells, particularly if the water was not agitated in any way, very soon died; but if placed a little distance from the well, and especially if the water flowed over a weir or was otherwise agitated, very few of them died; while among the survivors two conditions were recognised, the most frequent being protruding eyeballs—"pop-eye"—and the other being the development of a blue sac attached to the gill. These conditions tended to disappear when the fish were removed a considerable distance from the well. Examination of the water taken carefully from the mouth of the wells showed that the water was radio-active and that a gas closely resembling the emanation of radium could be collected from it. Professor Farr stated these facts as a contribution to the physical and biological aspects of radium; he was not in any way concerned with the medical applications of that substance.

Dr. F. HERNAMAN-JOHNSON (Bishop Auckland) and Mr. W. DEANE BUTCHER (Ealing) also made some remarks bearing on the subject.

In opening a discussion on

The Therapeutic Uses of Radium,

Mr. DEANE BUTCHER said that the time had come when it was possible to make a sane and sober judgment as to the utility of radium, and the cases which were amenable to radio-action treatment. The cases specially suitable were small circumscribed lesions of the skin. He protested against the practice of excising a portion of a doubtful growth for diagnostic purposes, since this defeated the very object of radium treatment—viz., the destruction of the neoplasm without opening the lymph channels. In extensive or deep-seated cancer the most hopeful procedure was to introduce the radium into the interior of the growth by a surgical operation or to introduce the radium ion itself by Hasel's electrolytic method. Mr. Deane Butcher alluded to the theory of immunisation by radio-vaccination as a possible explanation of the good effects of radium irradiation. With regard to measurement, he considered that the dose should be defined accurately by the weight of pure metallic radium contained in the specimen used. The prescription for radium irradiation should include weight of metallic radium, area of applicator, thickness of screen, and duration of irradiation. He alluded to the approaching opening of the Radium Institute, which would afford to poor and rich alike in this country an adequate supply of radium. He hoped that the new radio-active substance, meso-thorium, would perhaps partially replace radium, and at all events help to mitigate the present radium famine.

Dr. J. H. SEQUEIRA (London) gave a short account of his experience of the use of radium at the London Hospital and in his private practice. He had treated nearly 400 cases, and emphasised the fact that in the majority of early cases of rodent ulcer the results were admirable. The factors which militated against success were the involvement of cartilage and bone and the spread of the disease into the orbital cavity. He was accustomed to apply the radium in the form of sulphate spread upon metallic plates.

Dr. FINZI spoke of the great value of proper filtration in radiumtherapy, which had to be modified both as to material and thickness depending on the requirements of the case and other circumstances. He also referred to the pronounced action of the beta rays of radium in the production of fibrous tissue.

Mr. W. HOLDER (Hull) spoke of the good results obtained by the use of small quantities of radium in cases of malignant disease as well as other local conditions. He emphasised the danger of making the intervals between applications too short.

Dr. G. WILLIAM HILL (London) referred to the results obtained in œsophageal strictures, which were very encouraging up to the present. He also asked for some standardisation of dosage.

Mr. COLIN CAMPBELL (Southport) also bore testimony to the good results that were to be obtained from the use of small quantities of radium, and he quoted instances of its great value in tuberculous ulcerations, and particularly in pruritus.

The prominent feature of this discussion was the evidence brought forth as to the large amount of good work that could be done with small quantities of radium, even though it be not of the highest possible activity.

Professor J. K. A. WERTHEIM SALOMONSON (Amsterdam) described and showed

A Modified Form of Benoist's Penetrometer

for measuring the hardness of the X ray tube. It might perhaps be more accurately described as a modification of Wehnelt's, which it more closely resembles. The improvement consists in the provision of two wedge-shaped pieces of aluminium, inverted to each other, so that as one is moved over the other the whole of the aluminium within the field of vision is of even thickness for all degrees of penetration. The instrument is being made in this country by Messrs. Newton and Co.

Dr. REGINALD MORTON (London) read a paper to introduce a discussion on

The Present Position of the X Ray Treatment of Malignant Disease.

He considered that the present time was a very good one to take stock of our position in this respect, but in connexion therewith he felt there were several points that wanted clearing up, and upon these he particularly invited discussion. Assuming that our object is to destroy or otherwise remove the cancerous cells, how far beneath the surface is the X ray method capable of bringing this about? Owing to the fact that the therapeutic value of the rays fell off very rapidly as the penetration increased and from observation in other ways, he was of the opinion that this could not take place to any appreciable extent beyond one-half inch from the surface of the growth. He considered that it was only those rays which were stopped and absorbed by the tissues that produced any effect upon them. He regarded the introduction of filters as one of the most important events in the history of radiology. He considered the non-metallic filters the most useful for this particular class of work. In the matter of dosage he had tried different methods, but now favoured fairly liberal doses given at comparatively short intervals. Massive doses at intervals of a week or so had given very poor results. He also invited an expression of opinion as to the relative value of the method in sarcoma and in carcinoma. In his own experience cases of carcinoma had so largely predominated that he found it difficult to draw a comparison. It was impossible to say how any particular case would respond to X ray treatment, but cases of carcinoma did so more evenly than sarcoma and also more favourably, though among the latter class he had one of his most brilliant results. It was, however, always possible to tell after a few applications how the case was likely to respond to the method, and for this reason he considered a trial course of treatment advisable in all cases. Summing up, he stated that the influence of the method upon malignant disease was a most distinctly favourable one—pain was relieved, the rate of advance was

greatly reduced and even arrested for a time, ulceration and accompanying discharge were checked, life was prolonged, and the patient made more comfortable in nearly every way. Unfortunately, treatment by any form of radiation gave us no control over metastasis. If we were to make any decided progress we must meet this difficulty to some extent at least. With this in view he made a plea for a closer coöperation between the surgeon and the radiologist than had existed up to the present. Taking operable cases first, he advised that a massive dose of X rays should be given to the site of operation before the wound was closed—a perfectly feasible procedure—and further X ray treatment as soon as the patient could bear it, carried on at intervals for a year or more. With regard to cases usually declared to be inoperable, the surgeon should not wash his hands of the case, as is so frequently done, but should consider whether it is not possible to remove the more superficial parts so as to allow the rays to get more or less directly at the part that really matters—the advancing margin.

In the discussion that followed most of the speakers were in agreement with the main points raised in the paper.

Dr. FINZI was not so sure that radiations which were unabsorbed did not produce some effect on the cells by the mere act of passing through.

Professor WERTHEIM SALOMONSON considered that the results of the X ray treatment of malignant disease were not encouraging as a whole, but admitted that the more superficial cases at times did very well.

Mr. J. HALL-EDWARDS (Birmingham) considered that only in the most severe cases should massive doses be given, but in ordinary conditions he thought mild doses repeated daily or on alternate days gave superior results.

Dr. J. DELPRATT HARRIS (Exeter) related his experience with a case of sarcoma of the cheek which seemed to resist ordinary treatment and he decided to give a very massive dose. He administered the equivalent of 18 Sabouraud pastille doses, the sitting lasting nearly six hours. An aluminium screen, ½ mm. thick, was placed between the skin and the tube. The tumour rapidly shrank and gave every promise of doing well. No bad results were noticed from the massive dose.

Dr. W. IRONSIDE BRUCE (London) also gave his experiences with very massive doses of the X rays, and felt that the method gave promise of good results in this class of disease.

Dr. MORTON suitably replied.

Dr. IRONSIDE BRUCE read a paper on

Pyelography and the Use of Collargol in the Diagnosis of Diseases of the Urinary Tract.

He said that collargol forms a perfectly inert solution which is opaque to the X rays. In cases of suspected dilatation, for instance, of any part of the system this part is filled with the collargol solution and the part radiographed. The work had been done in conjunction with Mr. J. W. Thomson Walker, whose paper was published in THE LANCET of June 17th, 1911.

At the afternoon session Mr. W. ARMSTRONG (Buxton) reported the results of his treatment of over 600 cases by

Radium Water

by means of drinking, inhalation, and bathing; the two latter in conjunction with oxygen. He showed that the radium emanations were eliminated in order of quantity by the lungs, skin, and kidneys. He described the increased excretion and the greater amount of the body poisons carried off in the breath, perspiration, and urine; also the increased activity of the various digestive ferments, and the hastening of purin body metabolism, and of the excretion of uric acid. He gave examples of most satisfactory results in cases of gout, rheumatism, arthritis, neuritis, diabetes, Bright's disease, high blood pressure, and neurasthenia. Great stress was laid upon the value of the radium oxygen both in high arterial tension, insomnia, and skin trouble of nervous origin. Mr. Armstrong summed up as follows: (*a*) That the successful treatment of diseases by radium water demanded a high dosage; (*b*) that these large doses can be given without the least fear of ill-effect; and (*c*) that two points stood out as regards the value of this treatment: (1) the great increase in nerve strength and vitality; (2) the very considerable quantity of poisonous matter expelled from the body.

A Review of Radium Therapy.

Professor S. SAUBERMANN (Berlin) gave the section a fairly complete review of all the work which forms the basis of to-day's radiumtherapy for internal use, and went into some detail regarding the physical, chemical, biological, and physiological properties of the emanation. His purpose was to prove that there really exists a close connexion between the emanation and certain processes which take place within the human organism. A large number of tables and experiments which he mentioned suggested that a quantity of energy is developed by the atomic disintegration of radium into a series of decomposition products, and though the emanation itself is absolutely inert, its mere presence brings about chemical reactions which are otherwise inconceivable, or which would normally be greatly accelerated. From this is derived the conclusion that biological and physiological influences upon living cells and organisms must take place. Professor Saubermann stated the following as "biological facts with regard to radium emanation," giving the date of the research and the name of the observer:—

1903—The preparation of radio-active water by means of radium for biological research. (Saubermann.)
1904—Radium emanation (R.E.) increases autolytic fermentation. (Neuberg.)
1905—R.E. increases the activity of the peptic ferment. (Bergell and Bickell.)
R.E. increases the activity of the pancreatic ferment. (Braunstein and Bickell.)
1906—R.E. increases the activity of lactic acid fermentation. (Richet.)
1907—R.E. increases the peristaltic actions. (Deutelmoser and Saubermann.)
1908—R.E. increases the solubility of uric acid salts (urolytic fermentation). (Deutelmoser and Saubermann.)
R.E. increases the glycolytic fermentation. (Deutelmoser and Saubermann.)
1909—R.E. increases the activity of diastatic fermentation. (Edelstein.)
1910—R.E. penetrates the skin into the body. (Engelmann and Strassburg r.)
1911—R.E. effects leukopenia. (Noorden and Falta.)
R.E. increases the coagulability of the blood. (Lazarus, Saubermann, and Velden.)
R.E. penetrates every animal membrane and tissue.
R.E. acts by its disintegration products.
The co efficient of solubility in blood is 0·20. (Lazarus and Saubermann.)
The greater radio-active quality of mountain air plays an important part in human life. (Aschkinass and Kaspari.)
The radio-activity of the air is a matter of importance to the human organism. (Saake.)
In southerly winds (Sirocco, Samun), the physiological action of which is well marked, the radio-active capacity is exceptionally high. (Gockel, Aschkinass, and Kaspari.)
All increased radio-activity in mineral springs makes itself felt in the human organism, a physiological factor which cannot be ignored. (Bergell, Bickel, and Himstedt.)
The higher the emanation capacity of a given spring, the more striking are the physiological results. (Mache, Curie, and Laborde.)
Water rendered radio-active has a most unusual influence upon the human organism. (Bergell, Bickell, and Deutmann.)
Owing to inhalation of emanation in the galleries of the St. Joachimsthal pitchblende mines, where the air is radio-active, gout, rheumatism, and neuralgia do not occur. (Gottlieb, Kemen, and Deutwitz.)
Occurrence of bladder activity, increased diuresis, and exacerbation of pains in baths with radio-active water. (Neusser, Saake, and Wilke.)
R.E. has a favourable effect upon organic metabolism. (Deutelmoser, Saubermann, Silbergleit, and Kijokki.)
Importance of radium emanation in disturbed organic metabolism. (Krieg.)
Increase in the excretion of urea up to 34 per cent. and of uric acid up to 14 per cent. (Wilke.)
The cardiac blood pressure, diuresis, excretion of urea and uric acid are influenced. (Deutelmoser, Saubermann, and Krieg.)
R.E. lessens blood pressure and cardiac activity. (Deutelmoser and Saubermann.)
A certain percentage of radio-active electric ions in the air is absolutely necessary, especially for gouty and rheumatic patients. (Steffens and Grabley.)
R.E. has the power of keeping the uric acid compounds in their easily soluble forms. (Deutelmoser and Saubermann.)
R.E. acts both as a powerful nerve sedative and as a hypnotic. (Pollack and Dreuw.)

"If emanation will activate ferments, a very broad basis for a scientific therapy has been established," said Professor Saubermann, who considered that a normal secretion and mutual activation of ferments are indispensable to the synthesis of simple, classical compounds derived from nourishment. His clinical results so far obtained cover, he said, "as they logically should, the vast field of body metabolism, and have proved of great benefit in the treatment of gout, rheumatism, diabetes, nephritis, high blood tension, and other complaints of similar character, as shown by numerous leading authorities, such as Bergell, Lazarus, Schiff, Bickel, Peters, Sandmayer."

LARYNGOLOGY, OTOLOGY, AND RHINOLOGY.

THURSDAY, JULY 27TH.

President, Mr. FRANK MARSH (Birmingham).

Mr. MACLEOD P. YEARSLEY (London) and Dr. HUGO FREY (Vienna) opened a discussion on

The Treatment of Chronic Adhesive Processes in the Middle Ear.

Mr. MACLEOD YEARSLEY said the magnitude of the subject necessitated limiting the conditions to be discussed to post-suppurative and post-catarrhal processes, to the exclusion of the labyrinthine capsule. Accuracy of diagnosis was important, and was dependent upon the careful consideration of three factors—namely, symptoms, results of physical examination, and evidences afforded by careful functional testing. Regular inflation of the ear was of value, and inflation from a catheter was to be preferred before that from an indiarubber bag on the grounds of cleanliness and also because the former method could be better controlled by the operator. The Valsalva method was to be deprecated. Nasal treatment was to be encouraged, especially with regard to abnormal conditions in the fossæ of Rosenmüller. Prophylaxis, he considered, would be the treatment of the future. Attention should also be paid to conditions outside the ear, such as pyorrhœa, intestinal toxæmia, and gouty tendencies. The use of thyroid extract in his experience had been attended with uniform failure, and the use of thiosinamin, or its derivative, fibrolysin, had been disappointing. Oto-massage was of value; he was in favour of short piston strokes and rapid vibrations. The operative methods of treatment included mobilisation of the malleus, incision of the posterior fold of the tympanic membrane, tenotomy of the tensor tympani and the stapedius muscles, exploratory tympanotomy, the division of adhesions, the removal of portion of the membrana tympani, and ossiculectomy. Some of these were useful. The value of ossiculectomy was doubtful; possibly the operation was unjustifiable. Whatever method of treatment, whether non-operative or operative, might be employed, a considerable number of cases remained unrelieved. For these, two courses were open—lip-reading, or the use of an artificial aid to hearing. As regards the latter, there was room for valuable research. There was much to be done in the investigation of the relative uses of electrical aid, such as the combination of telephone and microphone; but such investigation required the coöperation of the expert electrician and the otologist.

Dr. FREY spoke of the difficulties that had arisen from the loose terminology in present use. In a subject such as that they were dependent upon the experiences gained by others and the records of those experiences, hence the difficulty in classification and the confusions that had arisen. Such terms as chronic catarrh, dry catarrh, and chronic adhesive processes of the middle ear had been loosely used and interchanged. He pleaded for the distinction of oto-sclerosis from chronic adhesive processes and for more exact reports and better diagnosis by contributors to the literature. Dr. Frey gave a brief account of the etiology of the disease and discussed and compared the various methods of treatment under the following headings: prophylactic measures, local (mechanical and electrical) treatment, constitutional treatment, and operative measures. He urged the importance of inflation of the ear, inasmuch as even minute changes in the Eustachian tube could materially affect the hearing. He did not commend the injection of fluids into the Eustachian tube. A new method of treatment which he thought might ultimately be found to be of service in reducing the subjective noises was the use of light rays. Mobilisation of the stapes, he considered, was both dangerous and useless.

Dr. ANDREW WYLIE (London) referred to the hot-air method of treatment and exhibited an apparatus, which he had shown previously to the section when the Association met in Belfast, for producing hot air by means of the electric current. Since previously exhibiting the apparatus it had been simplified and reduced in bulk. The difficulty of controlling the heat occasioned by the hot air passing through a metal Eustachian catheter had been overcome by using a catheter made of vegetable matter.

Dr. W. JOBSON HORNE (London) pointed out that even in the worst of the cases of deafness under discussion there was a residuum of hearing, and it was important to encourage the patient to cultivate that residual hearing. Therefore one was justified in urging a course of treatment even in those which appeared to be the most hopeless cases. One indication for the treatment of nasal obstruction or narrowing was marked relief following the use of the nasal catheter; but should the use of the nasal catheter yield a negative result that was not, in his experience, evidence of nasal treatment being contra-indicated. Prophylaxis and special attention to the naso-pharynx in early life were strongly indicated. It was remarkable, in his experience, how the sudden onset of suppuration in the middle ear in a long-standing case of chronic dry non-suppurative catarrh would at times leave the patient with a marked improvement in the hearing. He considered that the multiplicity of remedies was in itself a blot upon their methods of treatment of that particular form of ear disease. He thought the time had come for more attention to be paid by themselves in coöperation with expert electricians to the manufacture and sale at reasonable prices of instruments to aid the hearing.

Dr. P. WATSON-WILLIAMS (Bristol) said that even modified success was of importance in the cases under discussion. Adenectomy must be undertaken not only for the relief of nasal obstruction, but also in cases without the adenoid facies for the relief of nasal and Eustachian catarrh. As regards the advisability of removing the drum and the malleus, if a perforation of the drum improved the hearing then he thought one would be encouraged in the operation.

Mr. H. F. MOLE (Bristol) spoke of his experience with fibrolysin, and was desirous of hearing which cases were to be selected for the mobilisation of an adherent malleus.

Mr. W. S. SYME (Glasgow) spoke in favour of extending nasal operative treatment, especially where a naso-pharnygitis existed. In all cases the condition of the internal ear must be previously taken into account. As regards fibrolysin, in cases of pure adhesive middle-ear catarrh he had met with no improvement, but in cases of post-suppurative conditions remarkable results had been obtained. In reading the reports upon school children he had been struck by the proportion of cases in which the diagnosis of enlarged tonsils had been made without any mention of adenoids. The natural inference was that the tonsils had been removed by the practitioners, and the more important factor, the adenoids, had not been removed. From the point of view of prophylaxis that was to be regretted.

Dr. L. H. PEGLER (London) supported the theory of a nerve influence helping in the operative nasal treatment of cases of deafness.

Dr. A. BRONNER (Bradford) argued that by preventing catarrh one would help in preventing the resulting contraction of tissues. The majority of people in this country had nasal catarrh once or twice or more often in the year. This he attributed to the sudden onset of fog and damp in the course of the night whilst sleeping with an open window, and he advised a return to the old-fashioned nightcap as a preventive. All elderly people who are deaf, he considered, should take iodide of potassium in small doses not for weeks or months but longer.

Dr. DAN MCKENZIE (London) pointed out that there were other means of making the tissues hyperæmic besides the hot-air treatment, such as Bier's method or the application of irritants to the drum. He suggested a wider rubber tube in Dr. Wylie's apparatus.

Mr. F. W. SYDENHAM (Walsall) recorded his experiences with the use of fibrolysin. He had observed improvement in 3 out of 12 cases in which he had used it. In one case suppuration inadvertently supervened and with great benefit to the patient's hearing power.

Mr. H. TILLEY (London) said that fibrolysin in his hands had been of no use whatever. The Eustachian catheter he regarded as a test or indication for nasal operative measures. If no improvement in hearing resulted from the use of the catheter, then he considered no benefit would be afforded to the hearing by nasal operation.

Dr. J. GIBB WISHART (Toronto) considered that even if the use of the catheter gave a negative result as regards the hearing, one would not be justified in sending away the patient without treatment if nasal catarrh or post-nasal catarrh existed.

Dr. H. J. DAVIS (London) supported nasal douching. He was in favour of Eustachian injections and the administration of iodide of potassium.

Mr. YEARSLEY and Dr. FREY replied.

The PRESIDENT summed up the discussion. From the opinions that had been expressed he gathered that the general view of the meeting was that if temporary improvement to the hearing could be obtained by inflating the middle ear then nasal treatment should be adopted, and even if not much improvement followed inflation, then nasal obstruction should be dealt with. The residuum of hearing should be cultivated, and, if possible, improved, and the patients encouraged to keep up their general health. Operative measures upon the ear itself appeared to stand very much where they were before.

Dr. JOBSON HORNE exhibited

A Simplified Insufflator for Use in the Treatment of Diseases of the Throat, Nose, and Ear.

The instrument consists of glass-tubes of various lengths, shapes, curves, and calibre to meet the requirements of the regions in which they were to be used. The distal end of the tubes is roughened on the inner surface for an inch or more. This roughening of the inner surface of the tube permits of the powder being retained *in situ*, and also of a known quantity of powder being used. The advantages claimed for this insufflator are: simplicity, cleanliness, simplicity of auto-insufflation, precise dosage, and cheapness. The instrument has been made by Mr. F. Rogers of Oxford-street.

MEDICAL SOCIOLOGY.

THURSDAY, JULY 27TH.

President, Dr. GEORGE REID (Stafford).

Hospital Reform in Relation to the National Insurance Bill

was the subject upon which distinguished speakers, medical and lay, addressed the Section at its second session. The question was dealt with both from the points of view of the medical staffs and of the governing bodies of hospitals, and there was evidently some difference of opinion as to whether hospitals will be wise in accepting grants-in-aid from the State in respect of insurance patients. Dr. GEORGE REID again presided, but the attendance was still disappointing—it was suggested because the Section had been "skied." The meeting-place was on one of the topmost floors of the University buildings.

Dr. LAURISTON E. SHAW (London), in a brief opening paper, asserted that the Insurance Bill must profoundly alter the position of the hospitals. Even if the Bill did not pass, the prominence given by its discussion to the unsatisfactory provision of medical treatment for large sections of the community must lead shortly to the institution of some alternative to the present chaotic jumble of indiscriminate charity, inadequately paid contract service, and a mutually unpopular Poor-law medical service. Assuming that the Bill would pass—modified, of course, in accordance with the strictly moderate demands of the medical profession—the hospitals would find there was still much work for them to do on a voluntary basis. The Bill provided only, except in the case of consumption, for ordinary domiciliary medical treatment. For other cases further provision of some sort must be forthcoming, and it seemed probable that, at any rate at the outset, it would be made by means of the voluntary hospitals. It had long been recognised that the attempt to combine the dual function of ministering to minor ailments, and at the same time dealing with cases requiring the highest resources of medical and surgical skill, had handicapped the development of the professional side of the hospital, while the avoidance of imposition and abuse in these conditions had become quite impossible. The provision of insurance for ordinary treatment for a large section of the present hospital *clientèle* should greatly simplify the selection of suitable cases. Inquiries into the economic position of the patient would be reduced in many cases to determining the status of the patient under the insurance scheme, and there would be *primâ facie* ground for insisting that the hospital should exercise its proper function of providing special medical service only. Dr. Shaw laid stress on the necessity from both professional and social points of view of dealing with the insured persons at the hospital on a consultative basis in coöperation with the insurance doctor. From the professional point of view it might well be regarded as a breach of medical etiquette for a member of the hospital staff, knowing that the insured person had definitely engaged a medical practitioner to attend him, to undertake his treatment except with the sanction of, and in coöperation with, that attendant. To deal entirely on independent lines with another man's patient, even in the sacred name of charity, could hardly be tolerated in the altered circumstances created by the Bill. From the social side the public, which had to maintain the insurance fund, was equally interested with the profession in securing coöperation between the insurance and hospital doctor. It would be obviously unfair and detrimental to the insurance service (Dr. Shaw went on) that the hospital should be in direct competition with it. The fact that hospital treatment was given by men who were consultants and usually charged private patients higher fees than the insurance doctor did, the glamour of the place, and the ritual observed in teaching students would, even if the actual service were inferior—instead of being as a rule, for suitable cases, superior—strongly impress the patient with its superiority. To avoid disaster systematic coöperation was essential. On the question of the nationalisation of hospitals Dr. Shaw said that while believing that in the interests of medical research and education the voluntary system should be maintained, he recognised that its continuance was imperilled. The transformation of voluntary hospitals into truly consultative institutions, taking no independent part in the treatment or investigation of disease, but coöperating always with institutions or private practitioners undertaking ordinary medical treatment, would provide them with a new lease of useful life, and would probably postpone indefinitely the nationalisation or municipalisation of that higher class of institution which was capable of adopting that line of professional work. Even if the hospitals did become nationalised, it would still be essential to define their relation to the insurance service. For the State to provide side by side an institutional and a domiciliary service, and to allow the patient to chose which he would use, would be a most unreasonable and unbusinesslike proceeding. Unless the voluntary hospitals would relinquish voluntarily all treatment such as was to be provided by the insurance scheme, and would coöperate with its officers in providing on consultative lines the additional special professional help which they were best fitted to provide, they would seriously handicap the insurance service and imperil their own future as independent institutions.

Mr. J. COURTNEY BUCHANAN (secretary of the Metropolitan Hospital) contributed a paper on

The Future of Voluntary Hospitals.

He urged that hospital managers should follow the wise course of the British Medical Association and set themselves to define beforehand the work their experience taught them they could do best. After touching on the effect of the Bill in drying up the sources whence hospitals derive their funds, Mr. Buchanan declared that the introduction of a system of charging insured patients was inevitable. In future hospitals would be forced to act solely in a consultative capacity towards the poorer classes. Trivial cases need no longer be treated at the hospitals; these would be seen by the insurance doctors. As he understood, the doctors would prefer to see the insured patients at some centre; these might be institutions conducted very much on the lines of provident dispensaries. These should be grouped around and be in touch with voluntary hospitals. School medical treatment might also be carried out in them. In his opinion it would be little short of a calamity if hospitals were subjected to any municipal control, but he could see no objection to hospitals being paid for work done for the insurance authorities, or even to State grants-in-aid for specific purposes, always provided that if the hospitals had to be subjected to public inspection it was carried out by experienced people. A central council might be established for this purpose; it would leave hospitals free to develop their own particular characteristics, while securing uniformi in matters where uniformity was really desirable, suc methods of admission, &c. The day had gone by, he when the provision of help for the sick would suffi enough money for the hospitals' support. The able ground for hoping that the hospitals maintained by voluntary contributions lay i that the more expensive forms of medical t advancement of medical education and s

now held for wealthy and philanthropic people. The future policy of the hospitals should be to show clearly that the work they did was for the benefit of the whole community, and for this purpose to maintain their special services in the highest perfection.

Mr. NEVILLE CHAMBERLAIN (Birmingham) contributed a paper on

The Reform of Out-patient Departments of Hospitals,

remarking by way of preface that while the Insurance Bill would render impossible the remedies he had in mind before its introduction, it would also, he hoped, remove in large part the evil those remedies were designed to meet. Probably everyone would agree that the work of out-patient departments was the least satisfactory part of modern hospital routine, whether looked at from the point of view of the hospital, the medical profession, or the patients who came to the departments for treatment. Instead of confining themselves to consultation and cases of immediate urgency, as was intended originally, the out-patient departments, with their elaborate and expensive apparatus, their trained nurses and experienced consultants, had allowed themselves to be turned into great free dispensaries. Really serious and important cases were jostled and thrust aside by people with cut fingers or common colds, or, what was perhaps worse, by chronics whose chances of cure lay rather in careful nursing and home treatment than in periodic visits to a distant institution. The result was an ever-increasing crowd of applicants for relief with a corresponding diminution of the amount of time devoted to each individual. Hospital managers chafed under a sense that the money of the subscribers was being wasted, patients grumbled at the long waiting, while the medical practitioner outside bitterly commented on the difficulty of earning a livelihood in competition with an institution which was not run on commercial lines, but offered gratis the knowledge and experience he had spent his time and money in acquiring. Proceeding to consider remedies for this state of things, Mr. Chamberlain mentioned how difficult it had been found in practice at the Birmingham General Hospital to get the staff to sort out applicants for relief and advise trivial cases to apply to their own doctor, to a dispensary, or elsewhere. The only chance appeared to lie in applying pressure on the people themselves. Mr. Chamberlain outlined "an ideal system of medical relief" as follows:—

1. Every person should contribute towards the cost of treatment.
2. Every person should be attended in the first instance by his own doctor, but should have power to change his doctor at intervals.
3. Drugs should not be dispensed by a doctor but by a chemist or dispensary.
4. Patients requiring institutional treatment should be admitted to the hospital as in-patients, or should obtain consultation or treatment on the recommendation of any qualified medical man without the necessity for subscribers' letters, &c.
5. Paying wards should be established for those in better circumstances.

An endeavour had been made to fulfil some of these conditions in Birmingham by the establishment of a provident dispensary. Mr. Chamberlain described the methods of this institution, which a medical speaker later in the meeting paid the tribute of describing as free from the defects of most similar undertakings. Among the hindrances to the success of the dispensary Mr. Chamberlain mentioned the apathy of the medical profession and the stringency of medical etiquette which made no distinction between canvassing for a private individual for his personal benefit and canvassing for a properly managed provident institution primarily for the benefit of the members themselves. Medical men had failed to recognise the trend of modern legislation and to see that the only alternatives open to them were an extension of the provident dispensary system and some form of State interference. The growth of dispensaries had been checked and the consequence was that the community had been led to interfere more and more in medical relief. Already in Birmingham the number of beds in rate-supported hospitals far exceeded those in voluntary hospitals. The urance Bill, following the lines of previous legislation, brought the State at one bound to the doors of the me and by the introduction of the compulsory curre d rendered superfluous the provident dispensary. been sim e the effect of the new system upon the out- trolling the nts? He hoped it would bring about the metal Eusta esired. Every man would go first to his catheter mad came to the hospital first it would be easy

Dr. W. JOB t, and the staff would be haunted no the worst of th a residuum of h

longer by the bogey of a public scandal following on a "spiteful death on the doorstep." He did not think the expense or the numbers of the out-patient departments would greatly decrease. There would be a larger number of difficult, protracted, and expensive cases, but the hospitals would be relieved of the greater portion of the trivial cases which were now such a clog upon their working. Subscriptions, however, must decrease owing to direct taxation of sources of hospital income. He did not agree with a system of *per capita* contributions from the State as likely to give rise to disputes. He would like to see sums of money allotted to hospitals on the lines of State grants to universities.

Dr. E. D. KIRBY (Birmingham) read a paper on

Some Local Aspects of Hospital Reform.

In Birmingham, he said, the medical institutions had allowed themselves gradually to be perverted from charities into provident institutions. That was to say, the working classes had been permitted to subscribe to them for their own benefit. It might be regarded as an intelligent anticipation of the Insurance Bill, with the significant exception that no provision at all was made for any payment to the medical profession. In illustration of this statement Dr. Kirby gave an account of the history of the General Dispensary showing how the practice of compulsorily deducting a penny a week from workmen's wages towards the Hospital Saturday Fund had led to people claiming as a right services which were instituted as a charity.

Dr. J. B. BRIERLEY (Manchester), opening the discussion, remarked that the reason the medical profession had been dubious of provident dispensaries was that they had not been able to secure an income limit for members.

Dr. J. H. KEAY (Greenwich) thought the spirit animating the papers read augured well for hearty coöperation being secured between medical men and hospital managers in meeting the altered circumstances brought about by the Insurance Bill. As to the reform of out-patient departments, he thought a few prosecutions of well-to-do people who abused them would be highly effectual.

Dr. D. J. MACKINTOSH (Glasgow) said that the Bill would assist in doing away with hospital abuse if it existed. Voluntary hospitals had a hand-to-mouth existence at present, and they could not continue to exist unless funds were forthcoming. He objected to hospitals accepting grants from the State, but saw no difficulty in their receiving payment for individual cases.

Dr. J. H. TAYLOR (Salford) thought control of hospitals by the Insurance Commissioners would not be as objectionable as State control, because on the former body there would be medical representation.

Mr. JAMES NEAL (Birmingham), Dr. WALLACE HENRY (Leicester), and Mr. G. JACKSON (Plymouth) also took part in the discussion, all emphasising the point that if insurance patients in hospitals were paid for, the medical staffs could not be expected to give their services voluntarily.

The readers of papers then replied, and on the question of the method of payment, if it was found that the State must come to the aid of the hospitals if the Bill was passed, Mr. CHAMBERLAIN pointed out that the estimated loss of income at different hospitals varied widely. A *per capita* grant would therefore not compensate some of the hospitals for their loss.

NEUROLOGY AND PSYCHOLOGICAL MEDICINE.

THURSDAY, JULY 27TH.

President, Dr. EDWIN GOODALL (Mental Hospital, Cardiff).

The subject set down for discussion was

Trauma in Relation to Nervous and Mental Affections,

which was introduced by Dr. F. W. MOTT (London), who began by emphasising the importance of distinguishing between cause and coincidence of head injury in relation to nervous and mental disease, also of recognising that head injuries are not infrequently the result of nervous or mental disease. His experience was drawn chiefly from asylum work, and it was curious how few actual cases of head injury with trephining for it he had observed. Out of 20,000 cases there were less than 20 of this kind, and in a series of 2000 necropsies on insane cases there was only one. That head injuries might cause insanity was admitted, although it was of the first importance to elicit the details

of the family history in all such cases. Dr. Mott quoted the case of a shipwright who had fallen down a ship's hold and fractured the cranial base and vertex. The man was taken to Poplar Hospital, and eventually discharged with his mind somewhat affected. On coming under Dr. Mott's observation at Claybury a diagnosis of general paralysis was made, although there was no Argyll Robertson pupil. The patient gradually sank and died, and at the necropsy were found chronic basal meningitis, caries of the petrous bone, and internal hydrocephalus, also a choked optic disc on both sides. The association between the injury and the disease was apparent. On the other hand, a patient who fell 40 ft., fracturing his skull and sustaining a considerable loss of frontal lobe tissue, became irresponsible and immoral thereafter, and had to be transferred to an asylum. In his case there was a marked family history of insanity. Another case quoted was that of a child who had had a bad head injury, with fits and subsequent imbecility. Naturally the friends attributed these to the injury, but at the post-mortem examination microgyria and porencephaly were found, showing that the epilepsy and imbecility could not possibly be attributed to the accident. Dr. Mott quoted other cases, and took up the general attitude that the relation of head injury to insanity was very slight. In five years of his Charing Cross Hospital experience he had seen 65 cases of head injury, of which 22 died in hospital. He had been able to follow up 13 cases of severe head injury, all of which patients developed the characteristic symptoms of traumatic neurasthenia. Yet all eventually recovered, with the solitary exception of one who was transferred to an asylum. He had been able to get certain figures from the admissions to Bexley Heath Asylum. Of 7640 admissions there were only 16 males and 20 females in whom a possible relation of injury to insanity might be considered. But in every case the injury was contributory rather than primal. Dr. Mott quoted a number of instructive cases where the possible relation of injury to the development of general paralysis had to be considered, and went fully into the medico-legal aspect of these cases. He pointed out how head injury might easily be an accelerating factor in the development of nervous and mental disease, and quoted illustrative cases.

Dr. BYROM BRAMWELL (Edinburgh) said the chief difficulty in many cases was to determine whether the patient who had had an accident, and thereafter developed definite nervous symptoms, was nervously healthy at the time of the accident. This was true especially of epilepsy and general paralysis. Careful inquiry often showed that the patient was not in perfect nervous health at the time. Dr. Bramwell said he had seen cases of gumma of the brain, tuberculoma of the cerebellum, and other intracranial growths, apparently excited by injury, and it was quite reasonable to suppose that occasionally injury was the direct exciting cause. He had seen general paralysis resulting, as far as could be judged, from an injury. He entirely agreed with Dr. Mott that until the question of compensation was settled most traumatic cases of neurasthenia did not improve. He often told such patients that if they really wished to get better they must first settle all matters relating to compensation.

Dr. G. E. SHUTTLEWORTH (London) alluded to the frequency—indeed, the constancy—with which friends and others attribute the maldevelopment of defective children to injury either before, during, or after birth. Most parents were unwilling to admit hereditary tendencies, or that there were deeper causes for mental defect than accident. He could not agree with American statistics, which seemed to show that in 2 per cent. of mental defectives the result was due to attempts at abortion. He thought the attribution of mental defect to the use of the forceps at birth was erroneous; the timely use of the forceps saved many infants from the risks they would otherwise have run of sustaining head injuries. It was his experience, with regard to trauma in childhood, that after a fall out of a perambulator the parents began to observe their child more closely, and hence to notice symptoms which had hitherto escaped their observation.

Dr. J. S. RISIEN RUSSELL (London) called attention to the question more particularly of traumatic neurasthenia. He was bound to admit that sometimes trivial injuries resulted in extraordinarily severe symptoms, which could not possibly be simulated, and quoted illustrative cases. He thought, also, that compensation was due if pre-existing disease was accelerated by the injury or if its development was accelerated. He considered that the future of many traumatic cases depended on the age of the patient and the condition of his blood-vessels, especially those cases of severe traumatic neurasthenia where mental symptoms predominated. He agreed that trauma might definitely start a nervous lesion in a syphilitic individual. Further, the effects of a trauma, such as to result in actual structural damage, did not need to be immediate.

Dr. F. E. BATTEN (London) also referred to delay in the production of nervous lesions after an injury. He questioned very much whether actual organic disease of the central nervous system could develop after an injury. He could not subscribe to the views expressed by Dr. Bramwell and Dr. Russell in regard to this point. He had difficulty in imagining how a progressive weakness could follow an injury. He thought the condition after the injury was over would either remain stationary or would tend to improve. Dr. Batten was not able to agree with Dr. Mott that the Wassermann reaction was positive in practically cent. per cent. of general paralytics, and quoted cases in support of his contention.

Dr. NATHAN RAW (Liverpool) remarked how few actual cases of insanity followed head injury. In a series of 137 cases of general paralysis observed by him in the last 14 years, eight were attributed to injury. Careful inquiries, however, resulted in the fact that in six of the cases a definite history of syphilis was obtained, and in one other case general paralysis had been diagnosed before the injury occurred. The injuries alleged were as follows: severe injury to spine, fall of hammer on top of head, explosion with injuries to the face, fracture of cranial vault, fracture of frontal bone, severe kick from horse, general injuries to head, and concussion of brain. Necropsies were made in two fatal cases, and the typical appearances of general paralysis were observed, but no evidence of injury either to the skull or brain could be discovered. Dr. Raw concluded that trauma was not a cause of general paralysis *per se*, but that in persons who were predisposed to the disease a severe injury might accelerate its onset and cause a rapid progression of the symptoms with an earlier fatal termination.

Dr. W. J. MIDELTON (Bournemouth), Dr. D. COLQUHOUN (New Zealand), Dr. G. M. ROBERTSON (Morningside Asylum), Dr. J. G. SOUTAR (Gloucester), Dr. J. MILLS (Ballinasloe), Dr. W. SALISBURY-SHARPE (London), and Dr. EDWIN BRAMWELL (Edinburgh) continued the discussion. Dr. MOTT replied.

Professor B. PFEIFER (University of Halle, Germany) then read a paper on

Brain Puncture for Diagnostic Purposes.

He said that in cases of intracranial abscess, cyst, tumour, &c., it was often advisable to substantiate the diagnosis by the method of brain puncture, the technique of which had been considerably improved by himself. He thought that for diagnostic purposes the method was valuable, and it had received the support of various distinguished German surgeons, notably Krause and Borchardt. His method is as follows. The scalp over the area to be explored is anæsthetised with a spray, and a borer of 3 mm. diameter, worked by electricity, is used to drill through the bone. The needle, of platinum and iridium, 1 mm. in diameter, containing a silver wire inside, is introduced through the membranes and into the brain a given measured distance—say, 3–4 cm. The wire is then withdrawn and a syringe fitted to the needle, with which the operator's assistant aspirates into the tube a cylinder of brain tissue 1 mm. in diameter and 3–4 cm. long. This can be fixed, cut in serial section, and suitably stained. Professor Pfeiffer has found the operation practically painless, has performed it in a number of instances successfully, and reported a series of 13 new cases, in every one of which a positive finding was obtained. In one case death ensued in a few hours owing to the needle having punctured the artery of the corpus callosum, which, post mortem, was found to have been displaced from its normal position by a tumour. Sections were shown on the lantern of some of these cases, in which an exact local and histological diagnosis had thus been made; the tumours found included glioma, sarcoma, endothelioma, carcinoma, cholesteatoma, and cysticercus cyst.

Dr. E. F. TREVELYAN (Leeds) and Dr. R. T. WILLIAMSON (Manchester) discussed the paper.

OBSTETRICS AND GYNÆCOLOGY.

THURSDAY, JULY 27TH.

President, Professor EDWARD MALINS (Birmingham).

Professor PAUL STRASSMANN (Berlin), in opening a discussion on

The Present Position of Vaginal Operations in Relation to the Uterus and its Adnexa,

observed that laparotomy in gynæcological surgery is now not such a necessity as formerly. The following reasons may be cited in support of this thesis: (1) very large tumours of pelvic origin are far less common; (2) the tendency of modern treatment is towards conservatism; and (3) the percentage mortality of vaginal operations is less than that associated with laparotomy. Abdominal sections for disease of the pelvic viscera have certain well-defined disadvantages. In the first place, peritonitis is more frequent than after vaginal cœliotomies. This is in part due to the unavoidable contact with the intestines and omentum, and is to some extent aggravated by the Trendelenburg position. The trauma received by intestines and omentum in packing these structures away from the scene of operation is shown later by the presence of omental adhesions and stomach troubles. The discomfort arising from this cause is frequently diagnosed as hysteria, and serves but to emphasise the necessity for exercising great care in all manipulations of the omentum. Both peritonitis and intestinal paresis are largely avoided when the vaginal route is used. A further argument against laparotomy is the risk of hernia. Although this risk is to some extent obviated by the transverse fascial incision of Küstner and Pfannenstiel, it does not entirely eliminate the danger. Nevertheless, the abdominal incision certainly has a very definite sphere. The speaker recommended that it be employed for all tumours of doubtful origin. The vaginal operation for tumours requires an extensive differential diagnosis, and hospitals without a special gynæcologist will always prefer laparotomy. Fibromyomas should only be removed by the abdominal route when they are larger than the head of a newly-born child. At the most one-fifth of the operative cases of fibroids require laparotomy. Carcinoma of the cervix is best removed by laparotomy, except in the case of fat or elderly women or in the presence of severe constitutional disease, when the vaginal route is preferable. Carcinoma corporis uteri, on the other hand, may be dealt with quite satisfactorily by the vagina. Abdominal section is indicated also when appendicitis is suspected. Although Ott's speculum has removed some of the difficulties and rendered the vaginal operation quite possible, laparotomy is to be preferred. It is a point of considerable importance, therefore, in the diagnosis of cases of pelvic inflammation to eliminate the appendix as the *fons et origo mali*. Professor Strassmann then proceeded to explain the numerous advantages which the vaginal route offered. There was much less shock, and a corresponding smaller mortality. Convalescence was more rapid, and the after-effects due to adhesions or hernia entirely avoided. He was surprised at the disproportion that existed in numbers between obstetrical and gynæcological vaginal operations. The majority of vaginal sections became quite easy with practice, and even large cystic tumours can be removed with less trouble than is experienced in a craniotomy. For intrapelvic diagnosis Ott's speculum has provided the gynæcological surgeon with a very valuable weapon. In removing structures, however, it is better to rely on palpation. Disadvantages that have been urged against vaginal cœliotomy are: (1) the lack of sufficient room; (2) the danger of injuries to the bladder and ureters; and (3) the failure of primary union in the vaginal cicatrix, and the production of a weak scar and possibly hernia. Additional space for the vaginal operation may be gained by the use of perineal incisions and efficient retractors. Vesical and ureteral trauma is avoided by experience and the use of an "anterior flap" incision. Trouble with the cicatrix is more illusory than real. The indications for anterior and posterior vaginal incisions were clearly defined, and the steps of the "flap" operation carefully described with the aid of diagrams and instruments. The vaginal route offers exceptional advantages in the treatment of certain well-defined conditions. Tubal pregnancy, e.g., is easier to remove vaginally when the gestation is early and the rupture recent. Hæmatoceles should always be incised vaginally. Pelvic inflammatory exudates and pyosalpinx are better evacuated by a posterior vaginal incision than through a laparotomy wound. Drainage is much more easily maintained and the risk of general peritonitis reduced to a minimum. Convalescence is usually rapid in such cases. Again, in displacements of the uterus ventral fixations and Alexander's operation are but rarely called for. The ideal operation, in the speaker's opinion, is vesico-vaginal fixation. Great value is attached to a vaginal incision for exploratory purposes. Many pelvic ailments of women are seen where such an incision would permit of effective treatment—e.g., the separation of pelvic adhesions, stomatoplasty upon the Fallopian tubes, and the excision of small ovarian hæmatomata. Laparotomy for such conditions is too severe an operation, and associated with too many risks.

Dr. HERBERT R. SPENCER (London) congratulated Professor Strassmann upon his excellent paper, and was in complete accordance upon many points. He quite agreed with the conservative measures that were advocated, and he deprecated the resort to laparotomy in many cases of what is called the "acute abdomen." The sacrifice of many inflamed appendages by general surgeons is a scandal. A posterior vaginal incision in the majority of cases is all that is required. He did not agree with Professor Strassmann's references to the frequency of hernia after laparotomies, and he was disappointed to hear that catgut was recommended. In spite of Professor Strassmann's vigorous advocacy of the vaginal route, he thought that he still preferred laparotomy. The operation for fibroids is much "cleaner" by this means, and ovarian tumours can be removed entire—an important factor, since malignancy cannot always be diagnosed before tapping. Furthermore, it is much easier to control the bleeding from adhesions when the abdomen is open; and, finally, it is not infrequent to find sinuses existing between a pyosalpinx and intestine.

Dr. AMAND J. M. ROUTH (London) considered that vaginal operations are nowadays much neglected. He had had the advantage of being compelled to practise the method, as laparotomies were not permitted to gynæcologists at an institution to which he had the honour to be attached. He thought that the younger men favour abdominal work nowadays, because many of its dangers no longer exist, and the low mortality of vaginal operations is no longer a stimulus to counterbalance the difficulties. He had seen Ott's speculum in use, and thought that it had a useful sphere in the diagnosis of deposits, &c., but that it did not facilitate the removal of parts. He was quite in accord with Professor Strassmann on many points—e.g., the great value of vaginal drainage and the conservative treatment of salpingitis. In many cases of pelvic peritonitis all that is necessary is a posterior vaginal incision. Fibromyomata, if larger than a fist, are better removed through the abdomen. Carcinoma of the body of the uterus and early cases of carcinoma of the cervix can be treated by the vaginal route.

Dr. J. B. HELLIER (Leeds) remarked that he had employed the abdominal route for many years, and was much in favour of it. He believed in dealing with adhesions "by the light of day," and thought that all ovarian tumours, except the very largest, should be removed entire. One reason against vaginal sections that he particularly urged was the difficulty in checking bleeding. Furthermore, he did not think that infection of the general peritoneum was at all common in dealing with suppurating conditions in the pelvis through the abdomen, but he believed that vaginal drainage in these cases was the right procedure. Another reason that made him prefer the abdominal route was the fact that malignant disease of the intestines or other viscera is sometimes found in the course of a laparotomy.

Dr. C. E. PURSLOW (Birmingham) emphasised the danger of tapping ovarian tumours either during the course of laparotomy or vaginal section. He thought that rupture of an ovarian cyst might readily occur during the manipulations required to expose it by the vaginal route. Should the tumour be malignant or of dermoid nature the results might be disastrous. He also acquiesced in emphasising the extreme danger that some operators run in attacking from the abdomen a pelvic peritonitis secondary to abortion, &c. A vaginal incision relieved many of these cases at once. Exploratory vaginal cœliotomy might be advantageously employed in the diagnosis between some cases of pyosalpinx and tubal gestation.

Dr. A. W. RUSSELL (Glasgow) considered that hæmorrhage in the course of vaginal operations may be practically eliminated by the use of clamps, which are removed in 24 hours. He had used this method for years and had never

had any trouble with venous oozing. He always employed catgut ligatures and removed the whole of a gauze drain by the end of 48 hours after operation.

Dr. THOMAS WILSON (Birmingham) also advocated the use of catgut. He had never seen tetanus or secondary hæmorrhage resulting from its use. For uterine displacements he preferred Alexander's operation or some form of intra-abdominal fixation. For prolapse after the menopause he had had very good results from vesico-vaginal interposition. As regards the choice of operation for carcinoma, he could not agree that early cases should be subjected to vaginal section. He had frequently found that these "early" cases recurred, and advised, therefore, a radical Wertheim operation. Also, in "body" carcinoma cases only one in ten in his practice remained well after five years if dealt with by the vaginal route.

Dr. JOHN CAMPBELL (Belfast) observed that he was not quite convinced by the eloquent advocacy by Professor Strassmann of vaginal surgery. In cases of doubt he would always use abdominal methods. He was of opinion that uterine fibromyomata could be removed much more speedily through the abdomen than through the vagina, and this must have some effect upon the mortality-rate. He always preferred catgut for buried sutures, and hoped that the use of unabsorbable ligatures would soon become obsolete.

Mr. E. STANMORE BISHOP (Manchester) considered that the choice of route must depend upon the case, and be decided by the surgeon in charge. In the matter of ruptured tubal gestation, he thought that the most important factor in treatment was the rapid cessation of the hæmorrhage. This was not easily effected by the vagina and the ligatures were liable to slip. As regards post-operative cystitis, he did not believe the route employed had anything to do with it. The use of the catheter was the one and only cause.

Mr. E. W. SCOTT CARMICHAEL (Edinburgh) was of the opinion that no vaginal section for carcinoma was in accordance with scientific findings. It was quite impossible to excise completely the lymphatics by this route and he therefore strongly advocated abdominal operations for malignant disease. Ovarian cysts and severe degrees of pelvic inflammatory disease should be treated by laparotomy, but for the milder inflammatory conditions vaginal cœliotomy was satisfactory.

Dr. MARY THORNE (London) thought that the mortality of vaginal sections for fibromyomata was too high to prove conclusively the value of the route.

Dr. R. J. JOHNSTONE (Belfast) agreed with Professor Strassmann in that tubal gestation was treated most effectively by means of the vaginal route. He also preferred a vaginal incision for most inflammatory pelvic diseases. For most other conditions he regarded laparotomy as the operation of choice.

Dr. J. E. GEMMELL (Liverpool) regarded the abdominal route as being much cleaner and safer.

Dr. M. HANDFIELD-JONES (London) emphasised the danger, from the educational standpoint, of a too free advocacy of the charms of vaginal section. Amongst experts the operations undoubtedly were quite safe, but if they became general he was afraid that the mortality would at first be very high.

Professor STRASSMANN in reply, quite agreed that carcinoma should be attacked from the abdomen whenever possible, and a wide excision of lymphatics was indicated. He was surprised to hear that certain speakers disagreed with the use of catgut for buried sutures. If properly prepared with iodine he considered that it was quite safe. The material was very largely employed in Germany and he had never seen tetanus arise from its use. He thanked the section most heartily for the great interest that it had taken in his paper and for the excellent discussion that had followed.

ODONTOLOGY.

THURSDAY, JULY 27TH.

President, Professor F. EARLE HUXLEY (Birmingham).

A paper on the Incidence and Natural Arrest of Caries was read by the SECRETARY in the absence of the author, Dr. W. WALLACE (Glasgow).

Mr. A. S. UNDERWOOD (London) contributed

Some Remarks regarding Two Antral Cases.

He pointed out that the gorilla had septa in its maxillary sinuses which appeared to divide them into two separate chambers. In reality, however, inflation of the nasal duct, which was brought about probably by the vocal habits of the animal, encroached on the antral wall and gave it this appearance. He exhibited a human skull in which the nasal duct was inflated, simulating antral division, and spoke at some length on the difficulties of operation for relief of suppurative conditions of this cavity, and in his reply said that the accessory cavity was commoner on the left than on the right side—viz., in the proportion of 1 to 3—the usual position being that of the region of the third molar in each case.

The PRESIDENT, Professor JOHN HUMPHREYS (Birmingham), and Mr. HERBERT SMALE (London) took part in the discussion.

Mr. A. W. WELLINGS (Birmingham) then gave a lantern demonstration of

An Interesting Abnormality of the Dental Tissues.

In the ensuing discussion Mr. A. HOPEWELL-SMITH (London) expressed the view that the tooth tumour shown was probably due to fusion of two tooth germs, with a hollowing out of the intervening space; Mr. UNDERWOOD likened the condition to the folded character of the poison fang of the viper; and Mr. J. G. TURNER (London) suggested that it represented a calcified unilocular cystic tumour. Mr. HUMPHREY HUMPHREYS (Birmingham) endorsed the opinion of the first speaker.

Mr. J. G. TURNER, reading a paper on

The Pathology of Retained Teeth,

believed that teeth often remained buried in the substance of the bones of the jaws without producing any symptoms of pain or discomfort. When a communication and septic infection occurred between the retained body and the mouth, or the antrum, or the nose, neuralgia might occur. Skulls in the Anatomical Museum at Cambridge and the Museum of the Royal College of Surgeons of England had been examined, the result being that the probable factors in the production of retained teeth were failure of development of the bone of the jaws, the influence of sex, the displacement of tooth germs, the premature removal or undue retention of deciduous teeth, general and local diseases, and the presence of supernumerary teeth. He showed a number of slides and preparations to illustrate his subject.

This paper was discussed by Professor JOHN HUMPHREYS and Mr. HOPEWELL-SMITH, who inquired of the author whether his researches threw any light on the development of cystic fluid around these retained teeth; whether traumatic influences, such as those set up by foreign bodies in the mouth, had any effect without direct bacterial infection; and whether, by studying these pathological conditions, it was possible to explain the physiological processes connected with the normal eruption of the teeth.

Mr. A. BRITTEN (Birmingham) also spoke.

Later, the members of the Section adjourned to the Dental Museum, when Professor JOHN HUMPHREYS gave a discourse on the story of evolution of vertebrate life from geological times as shown by the most indestructible portions of the bodies of animals. Specimens of the teeth of ganoid and other fishes from the Silurian, Devonian, and Carboniferous epochs were passed round for examination, including orodus, strophodus, and the predatory sharks of the cretaceous periods. Reptiles were represented by the marine lizard ichthyosaurus, pliosaurus, plesiosaurus, iguanodon, and the miocene charcarodon. He concluded by briefly referring to the teeth of mammals of an archaic type—viz., palæotherium, hyopotamus, rhinoceros, hippopotamus, red deer, and the bison of pleistocene times.

OPHTHALMOLOGY.

THURSDAY, JULY 27TH.

President, Mr. HENRY EALES (Birmingham).

A discussion on

The Etiology, Diagnosis, and Treatment of Concomitant Squint and Heterophoria

was opened by Mr. CLAUD A. WORTH (London), who said that any historical survey would be out of place, but the names of four great workers in this field would be in everyone's mind—Donders, Javal, Priestley Smith, and Maddox. Convergent squint: In a normal-eyed person the two sets of

visual impressions received by the two eyes are fused in the brain into one picture. In order that fusion may take place the direction of the visual axes must correspond. The cerebral faculty of fusion determined the effort of the oculomotor apparatus to this end. When that faculty was perfect even gross displacement of the visual axes, such as could be produced by prisms, could be overcome, so a want of balance of the motor apparatus would not cause squint, but heterophoria. If the fusion faculty was temporarily in abeyance—e.g., when one eye was covered—the eyes would deviate. In hypermetropia there was a tendency to excessive convergence during accommodation, but in the interest of binocular vision this was checked. In forcible deviation, as in paralysis of an external rectus, there was persistent diplopia. Contrariwise, in the absence of fusion faculty there was no reason for accord in the visual axes, and any disturbing factor, hypermetropia, motor defect, or mental disturbance, caused squint. The controlling factor was referable to the brain; further than this one could not go. The onset of squint was most frequent in the second and third year. He thought that some fusion faculty was present and remained effective until particular strain, illness or school, rendered it insufficient in the face of ocular difficulties. The belief that squint was determined by motor difficulties was negatived by cases of motor imbalance, where so high a defect as 15° could continue without squint. Considering the amblyopia of squint, he held that at least 90 per cent. of amblyopia in squinting eyes was acquired. In the rare cases of amblyopia without squint there was usually a high degree of astigmatism in the amblyopic eye and none in the other eye; in these cases it appeared that the amblyopia arose from the selective use of the good eye. In the treatment of convergent squint he recognised three aims: (1) the cure of the "amblyopia ex anopsia," (2) the removal of the deformity, and (3) the securing of binocular vision. Measures for the attainment of the final result were: 1. Atropising of the fixing eye only; this was only of use when the squinting eye retained the power of fixation. 2. Occlusion of the fixing eye when the squinting eye had lost the power of fixation. There should be total occlusion of the eye for at least one month; more than that was rarely necessary or useful. 3. The exact correction of errors of refraction. He did not hesitate to do this at as early an age as three months, for it was now certain accommodation came into play at an early age. 4. Operation. As a rule this should not be attempted until all other means of rectification had failed. Simple tenotomy for the rectification of squint he did less and less; he relied now almost entirely upon advancement of one or both external recti. There were two varieties of divergent squint which had an entirely different origin. The first was associated with myopia of high degree, and was consequent on the increasing difficulty of maintaining excessive convergence. Since the eyes of school children had been systematically examined it had become less frequent. The second order he had called "neuropathic." It usually dated from infancy; it was occasional or constant, unilateral or alternating. There might be feeble fusion; more commonly it was absent. Only in the constant unilateral cases was there amblyopia; in others vision was perfect. Convergence was always defective, and the degree varied from day to day. The subjects of it were bright and intelligent but nervous. It was three times more common in females than in males. He held that in heterophoria there was a defect in the relative motor balance of the eyes kept in check by the fusion faculty. It was the reverse of squint. It was impossible in most cases to demonstrate any particular muscle defect, but the effect of it was manifest in an abnormal tendency to convergence, divergence, or vertical deviation. It was by no means uncommon to find that sufferers from "eye-strain," who had emmetropia in each eye, were deficient in motor balance, and that to this their trouble was due. Of the varieties of defect hyperphoria was the most troublesome, and the least common; in these last, for cases of moderate degree the use of prisms was invaluable, but for high degrees advancement of an inferior rectus was preferable.

Mr. H. H. B. CUNNINGHAM (Belfast) laid stress upon the hereditary or familial nature of squint; he had traced the characteristic in not a few families. Anisometropia in a more or less marked degree seemed a particularly effective ocular defect in determining a squint; the fusion faculty must be at a special disadvantage in such cases. On the general lines of treatment he was in agreement with Mr. Worth. On the matter of training, whilst he held instruments such as the "amblyoscope" and "diaphragm test" of the greatest value in children of fair age, something was wanted for very young children. For this purpose two colour pictures had been devised which, when looked at through red and green screens, showed which eye was fixing; by these pictures useful practice could be obtained. He agreed in the superiority of advancement over tenotomy, and in the importance of not including the artery of the muscle within the suture.

Dr. R. J. COULTER (Newport, Mon.) drew attention to those cases in which no error of refraction was found in early life, but later, after the existence of squint for some years, astigmatism appeared. He suggested that the abnormal pressure of the muscles in excessive convergence might induce the astigmatism.

Dr. J. B. STORY (Dublin) put the order of procedure in treatment as: (1) Correction of error of refraction; (2) occlusion of the fixing eye; and (3) advancement to correct deformity and permit of fusion training. As regards etiology, there were cases that he felt were not covered by current theories—cases where squint ought to have appeared, but in which there was none.

Mr. A. W. ORMOND (London) called attention to a record by Cheselden in the middle of the eighteenth century concerning the lack of appreciation of a patient at the restoration of his sight by cataract couching. It emphasised the fact that amblyopia did not appear unless vision was interfered with before it was properly established; once that was attained an amblyopia was unlikely to be complete at any time, and vision was recoverable. If vision was interfered with before it was properly established amblyopia tended to be marked and irremediable. He considered that every effort should be made to remove the squint by operative measures before training was undertaken.

Dr. W. B. INGLIS POLLOCK (Glasgow) said that in advancement it was necessary to exert particular care to obtain equal stress in the arrangement of the sutures, otherwise distressing hyperphoria might be caused.

Dr. MCREYNOLDS (Texas) had heard it said that American ophthalmologists over-emphasised the importance of muscle anomalies; he thought to-day's discussion dispelled that idea. Formerly there had been a large practice of partial tenotomies in the States; that had fallen into comparative disuse in favour of advancement. In one point their practice differed from that described by Mr. Worth; they did not sever, but folded and tucked in, the tendon.

Mr. N. BISHOP HARMAN (London) said the point in the paper of Mr. Worth that particularly interested him was the note concerning "neuropathic divergence." This defect he considered akin to such other cerebral defects as colour blindness and tone deafness; it was probably referable to an inherent weakness of the fusion faculty. There was great difficulty in treating it, just because the subjects of it never realised that they did squint. The wandering eye promptly returned to its duty when the patient was told of the squint, and they never could see it in their looking-glass! What they did not see they did not bother about. It was almost always the friends who objected to the squint. In the "diaphragm test" he had found a most satisfactory means of demonstrating the existence of the squint to these patients; they saw its effects for themselves, and that was the first step in any attempt to improve their condition. As regards heterophoria, he agreed in the influence these defects had in producing eye-strain, but he thought that this only held good for those people who did near work. He greatly preferred the practice of decentering the lenses worn by patients to secure prismatic effects rather than superadding prisms to the lenses. This was more convenient in prescribing, in manufacture, and in wearing.

Dr. K. PISCHEL (San Francisco) spoke of the superior advantage of sutures obtained from the tendons of rat tails in advancement operations.

Major R. H. ELLIOT, I.M.S., said that heterophoria as a cause of asthenopia was much more common in India than it appeared to be in England. Patients complained of its effects in India and remarked these disappeared when in England. He agreed with Mr. Bishop Harman that it was only necessary to correct the defect for the purposes of near vision.

Professor R. A. REEVES (Toronto) said that asthenopia from heterophoria was common enough in Canada. He found great benefit from the use of systematic exercise

with prisms. In advancement for squint there was a real danger of causing hyperphoria by inequality of the sutures. To avoid this risk he always stitched the shortened muscle to the old insertion of the muscle, end to end.

Professor PRIESTLEY SMITH (Birmingham) asked why Mr. Worth considered it better to advance the muscle to the edge of the cornea rather than in the manner Professor Reeves had just mentioned. The contrast of the old-time neglect of squint with their present-day careful educative methods was great, and this revolution they owed to the initiation of Javal.

Dr. N. H. PIKE (Cheltenham) said he had had good results in heterophoria by the use of prism exercises. The method was not nearly enough made use of.

Dr. T. HARRISON BUTLER (Coventry) said he wished to thank Mr. Worth for his operation; it had proved most satisfactory in his hands. He was in the habit of combining tenotomy of the opposing muscle with advancement, but the tenotomy was done so that its effect was temporary only or until the advanced muscle was secure.

Dr. ARTHUR GREENE (Norwich) asked what amount of improvement could be anticipated from atropising or occluding the fixing eye.

Dr. A. LITTLE (Bradford) asked how it was possible, as had been advised by Mr. Worth, that the exercise of the squinting eye should be carried out by the surgeon. How many sittings did it require?

Dr. A. HUGH THOMPSON (London) said that occlusion of the fixing eye for a long period was a serious handicap in the school life of the child. He had been in the habit of occluding the eye for only half the day, and with apparently good results.

Dr. J. GRAY CLEGG (Manchester) asked if training was of any use in securing restoration of vision in the squinting eye after the age of 8 or 9 years. He commented upon the existence of cyclophoria in patients without any indications of asthenopia.

The PRESIDENT said that to his mind the great change which had come about in their treatment of squint was due to the recognition that the amblyopia was caused by the squint, and was, therefore, ameliorable; and that it was not, as formerly held, the cause of the squint.

Mr. WORTH, in reply, said that as regards operation he did sometimes shorten and reattach a muscle to its old insertion, but in cases of considerable squint that did not give enough rotation, and it was necessary to advance the muscle to the corneal margin. It enhanced the action of the muscle considerably. He considered there was little risk of causing hyperphoria if the stitches were inserted parallel to each other and in line with the old insertion of the muscle. Occlusion of the fixing eye, he agreed, might occasionally be advantageously prolonged beyond four weeks, and at an older age than 7 years; but the willingness of the parents to take trouble had to be considered, and the risk of disappointment. At these late ages, when vision was improved, the gain was usually not great. For fusion training the most favourable age was from 3 to 6; 2 was too early to attempt it, and 7 mostly too late.

Dr. THOMSON HENDERSON (Nottingham) read a paper on

The Comparative Anatomy of the Ciliary Region.

He said that in the common farmyard quadrupeds (horse, cow, sheep, pig, cat, and dog) the regular arrangement seen in man did not obtain. The ciliary processes were not all the same size; they were smaller and more numerous towards the nasal side, and the smooth posterior part was absent. In effect it amounted to the prolongation of the retina forwards on the nasal side, a provision apparently correlated with the necessity for a wide field of vision towards the flank.

Mr. BISHOP HARMAN asked if Dr. Henderson had found any variation in this striking peculiarity in animals the shape of whose pupils were narrowed vertically, as the cat, or horizontally, as the horse or goat.

Dr. HENDERSON replied that there was no difference; both were alike in the advancement of the retina.

Dr. INGLIS POLLOCK read a paper on

The Treatment of Chronic Dacryocystitis.

He said that pathological examination of excised lacrymal sacs had enabled him to show that the subadenoid layer was greatly swollen and thrown into folds by a dense cellular infiltration. Such a condition was obviously unsuited to the older treatment of probing; rather, probing was likely to accentuate it and produce stricture. The dacryocystitis was secondary to a septic focus, most frequently in the nose, and its cure was best effected by regular and persistent lavage of the sac and duct. In private patients a short course of syringing usually effected a cure; but in hospital patients the results were not so satisfactory, probably because the condition was commonly advanced before they were seen. If after three months' lavage cure was not effected excision of the sac should be resorted to.

Dr. HARRISON BUTLER read a paper describing

A New Operation for the Extirpation of the Lacrymal Sac.

He said it was essentially a modification of Meller's operation. The site of the sac was rendered anæsthetic and anæmic by the injection of codreniue. The primary incision was through skin only; it took the form of a half circle with the centre at the canthus and a radius of 6 mm. The flap was carefully dissected up, avoiding buttonholing the skin or wounding the veins underlying the nasal side of the incision. The palpebral ligament was then isolated and the deep fascia split vertically so as to expose the sac. The sac was freed from its bed with blunt-pointed scissors and pushed down under the ligament. Then the canaliculi were severed, the sac drawn down towards the duct and twisted to the cord and cut off. The operation was bloodless and painless; no retractors were required, only sutures to hold back the flap and secure the ligament.

Mr. BISHOP HARMAN said that in his experience the difficulty of removing the lacrymal sac arose from attempts to see it. In this operation touch was better than sight. The bed of the sac could be perfectly defined by the sense of touch. To turn forward the contents of this groove, and then establish the actual position of the sac by means of a probe passed through the lower canaliculus into the sac itself, left no room for mistake. That done, he gripped the tissue between the fascia and bone and removed it bodily. The removed tissue contained the sac and little else. He did not hesitate to cut the palpebral ligament, and had never found any ill-effects for that procedure.

Mr. JOHN HERN (Darlington) agreed with Mr. Bishop Harman that removing the contents of the lacrymal groove was the best procedure. But he did not favour indiscriminate operation; most cases could be cured by syringing, preferably with weak iodine solution.

Mr. WORTH said that the practical abandonment of probing was a great advance; syringing should be the main procedure. Excision was a last resort.

Mr. CUNNINGHAM said enough attention was not called to the primary cause of dacryocystitis, which was commonly in the nose. Recently he had seen a case where cure of ozæna relieved the lacrymal trouble.

Mr. W. ALLPORT (Birmingham) said that in his experience it was never necessary to excise the sac unless intraocular operation was contemplated. His practice was to use silver styles, and their insertion and retention had the most beneficial effect.

Professor PRIESTLEY SMITH confirmed this statement of his colleague.

Mr. F. M. GRAINGER (Chester) also approved the use of silver styles, and in cases where abscess and fistula had supervened recommended the use of a little zinc paste to the interior of the sac; it destroyed the diseased mucosa and the fistula soon closed.

Mr. ORMOND said that styles were elusive things; he had once found three in one patient.

Mr. J. JAMESON EVANS (Birmingham) doubted if styles would cure the primary condition; excision secured a permanent result and relieved the patient of serious risks.

The PRESIDENT said he had tried both styles and excision; both procedures had their uses. He did not find any benefit in hollow styles over the solid. He agreed that more attention should be paid to the nasal conditions; when that was done sac troubles would probably disappear.

Dr. POLLOCK and Dr. BUTLER both replied.

PATHOLOGY.

THURSDAY, JULY 27TH.

President, Professor R. FRASER CALDER LEITH (Birmingham).

The PRESIDENT, in reopening the business of the meeting, stated that when the Committee decided on the subject for that day's paper they were divided as to whether a pure pathologist or a pure clinician should be asked to open the

discussion. They finally came to the conclusion that no one was better fitted for the task than Dr. Rolleston. He then asked Dr. H. D. Rolleston (London) to read his opening address on

The Pathogenic Action of Bacillus Coli.

Dr. ROLLESTON stated that it would no doubt be desirable to confine attention to the typical bacillus coli communis of the Escherich group, and as far as possible to exclude the intermediate group comprising B. enteritidis and the paracolon and paratyphoid organisms, and also the aerogenes groups. But this was hardly feasible at the present time, for many conditions and cases described as due to B. coli might really be examples of infections with coliform organisms of the intermediate group. The pathogenic action of B. coli was of great interest from the tendency in clinical medicine to regard the alimentary canal as primarily responsible for many diseases of obscure origin, such as rheumatoid arthritis, diabetes, &c. B. coli was widely distributed, rapidly invaded the body after death, and might be found in pure culture in cases not searched for anaerobic organisms. Great caution must be exercised before stating that B. coli was pathogenic in any given case. There was, perhaps, a possibility that the pathogenetic effect of B. coli might sometimes be underestimated rather than exaggerated. In Flexner's studies of terminal infections he found B. coli so often that unless there were special reasons he attached no pathogenic importance to their presence. Dr. Rolleston then stated that the agglutination test was not an efficient one in determining whether the B. coli found in pathogenic exudates was infective or no. He stated that Dudgeon in a long series of cases found it was extremely rare to obtain a well-marked agglutination reaction. Dudgeon placed more reliance on the opsonic and phagocytic indices. The association of B. coli with other organisms was on a different footing from the presence of B. coli alone. Dr. Rolleston suggested that the failure of antistreptococcal serum to check the course of puerperal infections might be due to the fact that in these cases the streptococci were often associated with B. coli. He discussed the clinical features of the reaction of the human infection by B. coli. In acute forms there was often high temperature with rapid oscillations, though experiments made with B. coli endotoxin showed a marked fall of temperature. He considered that in children, if malaria was excluded, rigors were almost pathognomonic of urinary infection with B. coli. In the chronic forms of infection with B. coli the long duration and liability of relapse after periods of quiescence were notable features. As regards hæmic infections with B. coli, he stated that there were probably less than 50 recorded cases in which the organism was found by blood culture. He mentioned three groups of cases: (1) resembling typhoid; (2) pyæmic; and (3) terminal infections, and invited discussion on the frequency with which septicæmia due to B. coli occurred in fatal peritonitis and appendicitis. Reference was made to Adami's view on the bearing of subinfection with B. coli on the etiology of pernicious anæmia, hæmochromatosis, and hepatic cirrhosis. Metchnikoff's contention that indol and phenol produced by B. coli caused visceral lesions and arterio-sclerosis was mentioned, and reference was made to the production of arterio-sclerosis by injections of cultures of B. coli.

Dr. WOODS HUTCHINSON (St. Louis) stated that people were now so taken up by the fact that the alimentary canal was responsible for so much disease that some even went so far as to advise extirpation of the colon. He stated that in hook-worm disease in America the opinion generally held was that the profound anæmia was due to the passage of B. coli and its products through the walls of the bowel *viâ* the worm-bites. He held that many so-called gouty disorders were due to B. coli infections, and not to disorders of metabolism. He thought diabetes might be caused by an ascending infection of the canal of Wirsung and so of the pancreas by the B. coli, and that in diabetes the toilet of the alimentary canal was nearly as important as diet. He thought that many diseases were hastened to their end by infection with B. coli.

Professor G. SIMS WOODHEAD (Cambridge) said there were great difficulties in determining whether B. coli was the real and only factor at work. Mixtures of organisms of a most complicated character were found in the alimentary canal, and it was difficult to say which was the offending organism. He drew attention to the work of Cobbett and Graham Smith on grouse disease. They found that there was a constant relation between the number of animal parasites found in the cæca of grouse to the number of B. coli that could be detected in the organs and tissues; observations made by himself on the parasites of the alimentary canal of certain of the lower animals bore this out. Another difficulty was the variation in the pathogenicity of B. coli, becoming parasitic and saprophytic according as it grew in the tissues, in the intestinal canal, or outside the body. He stated that the nearer to human origin the B. coli is, in water contaminations by sewage, the greater is its pathogenic power, and that as soon as B. coli left the intestines and entered the tissues, so it became more active.

Dr. J. M. BERNSTEIN (London) argued that from the point of view of the clinical pathologist he considered that in any given case the diagnosis of coliform organism was sufficient, and that it was unnecessary to state the exact type of coliform organism found. He said that if a vaccine was prepared from the organism found and the patient treated with it, the exact definition of the organism was unnecessary, and that the labour involved was more than he as a clinical pathologist, and not a pure bacteriologist, considered justifiable. He considered urine free from pathogenic B. coli if cultures of 5 c.c. remained sterile, and did not consider, as Dr. Emery suggested, that B. coli present in 1 litre was pathogenic.

Dr. GEORGE DOCK (St. Louis) said that it seemed to him that many of the problems in pathology were closely connected with B. coli infection. He suggested that in future work in the B. coli group precise identification of the germ should be made, and he thought Adami's hypothesis regarding so-called subinfection very attractive, and that Opie's work was very suggestive. He drew attention to the increase of virulence of B. coli in animals given small doses of morphine, and thought it was disadvantageous to use morphine in B. coli infections.

Dr. J. H. THURSFIELD (London) mentioned the difficulty clinicians and pathologists had in identifying B. coli infections, and said that what was now wanted from the scientific pathologist was a clear indication of the means by which the organisms found might be classified, in order that the clinician and clinical pathologist might be able to correlate the symptoms found with the different types. Dr. Thursfield stated that in his opinon the prognosis as regards symptoms in urinary infections was good; prognosis as to freedom of the urine from the B. coli was bad, and he had not known of an adult who had become free bacteriologically, though in children such results were more frequent.

Dr. J. W. SMITH (Newcastle) referred to a case of chronic general dermatitis with acute exacerbations every three or four weeks, and affecting practically all the cutaneous surface, the cause of which was with difficulty discovered. A catheter specimen of urine was examined and found to contain large numbers of B. coli. An autogenous vaccine was prepared and the patient treated with it with complete success. She was having at the same time alkalies and sour milk.

Dr. W. D'ESTE EMERY (London) thought that Dr. Thursfield was unnecessarily pessimistic with regard to the prognosis of urinary infections with B. coli. He admitted that in many cases it was difficult to get rid of the last few organisms from the urine, but this was accomplished in a fair proportion, and in the great majority all symptoms could be removed by means of vaccines. In children the number of successes was even greater, and vaccines were not always necessary. He had never seen B. coli in the blood or cerebrospinal fluid of patients suffering from B. coli infections, and insisted on the little value of agglutination tests in B. coli infections.

Dr. CHALMERS WATSON (Edinburgh) remarked that his experience of a large number of reports furnished to him by his bacteriological friends led him to agree with previous speakers that it was difficult to speak otherwise than of "organisms of the coliform group." He had found from reports sent to him that the morphological characters and bio-chemical characters of the bacillus from the same patient sometimes varied considerably at different stages of treatment. Dr. Rolleston had given a very comprehensive account of the clinical features of B. coli infections. Dr. Watson desired to emphasise the occurrence of symptoms in women in which asthenia was most marked usually associated with slight anæmia, and sometimes with slight enlargement

of the phalangeal joints, warranting the clinical diagnosis of rheumatoid arthritis, but which were the results of a B. coli infection. He considered the suggestion as regards gouty conditions very interesting, as he had long advocated the infective origin of this disease.

The PRESIDENT then addressed the meeting, and in congratulating the speakers on the excellency of the discussions, said that he thought disagreement between them on some of the points raised was the sign of a healthy condition, and that it was an inducement which weighed with the committee in choosing this subject for discussion. He regretted that the pure pathologist was so seldom able to meet his patients. He thought that the attention of clinicians should be drawn to the fact that great advances had been made as regards the exact determination of B. coli in the laboratory, and greatly deplored the suggestion that we should go back to the loose nomenclature of "coliform organism" in preference to the exact definition of the species involved. He considered the problem of the future to be the drawing up of definite bio-chemical and other tests, so that each worker would be sure that he was isolating the same organism. He believed that B. coli always bred true and would always give the same reactions.

STATE MEDICINE AND INDUSTRIAL DISEASES.

THURSDAY, JULY 27TH.

President, Professor ALFRED BOSTOCK HILL (Birmingham).

Dr. R. A. LYSTER (Winchester) read a paper on

The Need for Unification in the Public Medical Services.

He said that at the present time medical services were being provided for the public in the following ways: (1) By public health authorities; (2) by Poor-law authorities; (3) by county councils; and (4) by voluntary agencies. These services, he went on, although they overlapped to an astonishing degree in many ways, left many gaps. The overlapping caused a gross waste of public money, while the universal gaps represented a persistent and serious menace to public health. In reality there were other public medical services distinct from those he had already mentioned, such as factory surgeons, police surgeons, medical officers to the Post Office, and medical referees. These might be left out of consideration at first as they dealt with small sections of the public, but they would inevitably need coördination later. The central control of the public medical offices was in an almost equally chaotic condition, the Local Government Board, the Home Office, the Board of Agriculture, and the Board of Education all taking a hand in the supervision and control of purely public health matters, but each apparently acting quite independently of the others. The Local Government Board, in fact, appeared to be able to maintain the supervision and control of the great services—Poor-law and public health—in water-tight compartments without preserving any relationship with each other and without having any aims in common. From these causes resulted confusion and the obvious need for unification. Experience in the past ought to prove conclusively that independent authorities working on the same or similar lines led to wastefulness and inefficiency. The necessity for unification became apparent when one considered the unsatisfactory competition that took place between public health authorities, the Poor-law, and the voluntary agencies in the provision of institutional as well as out-patient treatment. The treatment provided, although unsatisfactory and often inadequate, was, as a rule, indiscriminate and liable to great abuse. Assuming that the need for unification had been proved, it now remained to suggest the lines upon which such could be arranged. The alternative principles to be followed were the combination of offices on the one hand and the unification of authorities on the other. The recent Order (1910) issued by the Local Government Board recommended that the medical officer of health could, with advantage, also hold the position of school medical officer, superintendent of the isolation hospital, certifying factory surgeon, police surgeon, public vaccinator, district medical officer, and medical officer to the workhouse. Such advice should have an important effect in educating public opinion, but the desirability, and especially the practicability, of such a method of unification must be carefully considered. An officer holding the above eight distinct and separate posts would be working under four authorities and with eight different conditions of appointment. The holding of the eight offices by one individual would not necessarily effect any coördination of work or bring about any real unification, so long as there were the different public bodies left to pursue their independent policies and to control his work. The advantage claimed for the above policy of the Local Government Board was that the officer could by these means be made independent of private practice. It was not likely, however, to have any extended trial owing to the opposition and mutual jealousies between the authorities chiefly concerned. The combination of offices might be found to be desirable as a sequence to the unification of authorities, but was not at all a promising procedure until that had taken place. The disadvantages of the present system did not arise from the multiplication of offices so much as from the number of authorities concerned. Each authority was independent, and, with the best of intentions, it was quite impossible for any coherent scheme of work to be arranged. The process of unification presented no insuperable difficulties, as all officials concerned could be taken over by the new authority, and the difficult problem of dealing with displacements from office would not appear. It would at once become possible to adopt a definite policy and to adjust the work so as to avoid overlapping, and yet leave no part of it undone. The fact that a scheme of unification was recently approved by the County Councils Association affords additional evidence of the desirability and practicability of such proposals. Recent developments in public administration indicated clearly that the unified service should be controlled by the councils of counties and county boroughs. If local committees were considered to be still desirable in county areas, it should be possible to arrange for a certain amount of local work to be given them so long as the organisation and coördination were carried out by the county council. Only when the unification of authorities was an accomplished fact would it be necessary and useful to discuss the advisability or otherwise of whole-time officials for public work. The gradual condensation of staffs by grouping together appointments as they fell vacant would be a simple matter if only one authority was concerned in such appointments, and the policy of the Local Government Board, as outlined in the Order (1910), would be quite easy to carry out. By very slight extensions of the plans suggested by the Local Government Board and the County Councils Association it would be possible to aim at the gathering together, under one medical officer, the work connected with general public health, school inspection, Poor-law out-door relief, inspection of midwives, work under Food and Drugs Acts, food inspection, prevention of river pollution, vaccination, organisation of voluntary work, &c. Local staffs would include sanitary inspectors and health visitors, while the central staff would consist of bacteriologist, analyst, veterinary inspector, and also under the control of the county council there would be an in-door staff consisting of resident medical officers of infirmaries, infectious disease hospitals, and sanatoriums.

Surgeon-General G. J. H. EVATT, A.M.S. (retired), urged the financial union of the charges for the Poor-law medical officers and the medical officers of health for the country as a preliminary step towards a closer union of those two classes of officials.

Dr. E. W. D. KITE (Sheffield) considered that certifying factory surgeons should have a central authority to report cases of unfitness.

Mr. HERBERT JONES (Hereford) protested that in the schemes for the unification of the medical service, with the county council as the centre and the county council medical officer of health as the administrative chief, the medical officers of health of the large districts were apparently ignored.

Dr. F. E. WYNNE (Leigh, Lancs) said his conception of the unification of the public health service was the establishment of a Department of Public Health with a Cabinet Minister at its head.

Dr. R. MURRAY LESLIE (London) was strongly in favour of some measure for the unification of the health service of the country. There was, no doubt, at present considerable wastage of effort on account of the overlapping of the work of the various State and voluntary health agencies. The office of the medical officer of health would naturally be the centre of the different local health agencies, and would be recognised as such.

Dr. A. E. LARKING (Buckingham) objected to the medical officers of health endeavouring to secure all the appointments. All schemes for the unification of the public health had the idea of subordinating the general practitioners to the medical officers of health. As a general practitioner, he thought that his class was the one to do the clinical work, and let the medical officer of health keep to his special work. The medical officer of health ought not to do any clinical work; he should devote all his time to public health work and to investigating into deleterious conditions reported to him by the practitioners of the district.

Dr. S. BARWISE (Duffield) said there was an entire misapprehension if it was imagined that the medical officer of health wanted in any way to undertake the work of treatment or interfere in the slightest degree with the independence of the general practitioner.

Dr. T. SHADICK HIGGINS (Birmingham) said that as a preliminary step to the unification of the medical services there should be unification of the present public health service.

The PRESIDENT said that the trend of the discussion seemed to show that all agreed that there was a need of unification, though in many cases some interests appeared to fear any extension of the power of the medical officer of health.

Dr. D. S. DAVIES (Bristol) read a paper on

Disease Carriers.

He said that in regard to State interference in the case of the chronic typhoid carrier, up to the present no solution as to what legislation was necessary and desirable had been arrived at.

Dr. E. W. GOODALL (London) said that however desirable it might seem to be to insist upon freedom from bacilli as a criterion of freedom from infection practice had shown that it was quite unnecessary and hardly worth the expense it entailed.

Dr. J. C. G. LEDINGHAM (London) agreed with Dr. Davies that some form of routine bacteriological examination of typhoid convalescents was essential before discharge and also that late control examinations should be made at the end of six months and one year.

Professor J. SPOTTISWOODE E. CAMERON (Leeds) said he was strongly of opinion that "return" cases of scarlet fever were most of them due to carriers. After eliminating all practical possibilities of inefficient disinfection—six weeks, nine weeks, or even longer before the discharge of the patient—there remained a certain number of cases in which the patient developed, when sent home, some nasal or other mucous discharge, although all such discharges were non-existent on being sent home and bacteriological examination showed no streptococci. They were greatly indebted to the bacteriologists. The debt would be infinitely increased if they would tell them what was the essential contagium vivum of scarlet fever.

Dr. H. J. EGERTON H. WILLIAMS (Sheffield) said that in his experience it was practically impossible to carry out a detailed and systematic examination of all cases of typhoid with the view of isolating carriers from the fact that trained assistance was insufficient.

THERAPEUTICS, INCLUDING DIETETICS.

THURSDAY, JULY 27TH.

Chairman, Dr. JAMES GALLOWAY (London), Vice-President.

In conjunction with the Dermatological Section a discussion was held on

Recent Developments in the Recognition and Treatment of Syphilis.

Mr. J. ERNEST LANE (London), who has been connected for more than a quarter of a century with the London Lock Hospital, opened the discussion, restricting himself mainly to a consideration of the clinical aspect of the subject. About seven months ago the introduction of salvarsan was a valuable addition to the therapeutic stock for the rapid relief of symptoms, though as a cure the speaker did not consider it displaced the time-honoured method of treatment by mercury. He wished to check immoderate enthusiasm and issue a warning not to expect too much of this new agent, which had certainly been over-estimated at first and had raised people's hopes that syphilis would now be easily curable. He quoted the *Times* of Dec. 19th, 1910, in this sense, stating that much disappointment has already resulted. In regard to the 120 cases which had come under his observation, the patients could not compare with those treated in the army either in physique, general hygiene, discipline, or in the opportunity for observing later effects; but experience showed that salvarsan was capable of checking most of the ravages of the disease, though lapse of time, at least three years, would be necessary before declaring a cure established. Infectivity would also in all probability be greatly diminished. It should not be forgotten that almost equally remarkable results followed the administration of mercury by intramuscular injection and inunction, which he still regarded as the mainstay in treatment. The demonstration of spirochætæ in the first stage was of the greatest importance in many instances that were formerly doubtful, and their discovery enabled vigorous treatment to be undertaken at a time which promised the greatest chance of success. He recommended the employment of 0·6 to 0·4 gramme of salvarsan, repeated in 14 days, though the primary lesion often cleared up after the first injection. He counselled the continuance of mercurial treatment thereafter for three years with intermissions. These injections involved some inconvenience, since the patient had to remain in bed at least 24 hours under close and skilled observation, as the reaction was sometimes severe and even alarming. It could not be foreseen in any individual, and might depend on arsenic intolerance. There was sometimes difficulty in reaching a vein, especially in women, as had been previously experienced in 1896 when intravenous injection of mercury was introduced. If the vein were missed serious and painful œdema and phlebitis resulted. Some fatalities had occurred, probably more than were generally known. He had had two such experiences in hospital, doubtless connected with the severity of the disease, but accelerated by the arsenic, and two others had recently come to his knowledge. Faults in technique resulting in admission of air or clotting also occurred, so the treatment was not without risk and discomfort. If undertaken by one thoroughly skilled, and followed by the administration of mercury, the treatment appeared ideal.

Captain L. W. HARRISON, R.A.M.C., said it was only natural in speaking of salvarsan to compare its effects with those of mercury in regard to safety of administration, rapidity of action, and permanency of results. In the majority of cases two years' persistent treatment by mercury was probably efficacious, but it made great demands on patience, and relapses and complications could scarcely be avoided. The dose needed nice adjustment, and intermissions of treatment might be necessary. His experience in the use of salvarsan at Rochester Row Hospital extended over 11 months, and the cases could be divided into (1) early primary cases, and (2) cases which had proved refractory to mercury. He presented tables showing every case treated, a complete account of relapses, those showing very striking results, and those in which the effects were not so pronounced. The first table of fresh cases treated initially by salvarsan showed a much more rapid decline of symptoms than was produced by mercury, whether tested by clinical appearances, bacteriology, or the Wassermann reaction. The second table, made up from cases refractory to mercury throughout the army, showed very striking effects of salvarsan, the symptoms commonly disappearing by the third or fourth day. His general conclusion was that a rapid cure was effected in both these classes of case, though it was yet too early to give an opinion as to ultimate and complete cure. Among 115 cases 18 relapses had been encountered. When a second injection had been given for recurrence of symptoms its effects were as strikingly beneficial as in the first. The subsequent instances showing a positive Wassermann reaction were more numerous than those of recurring symptoms, and he held it unwise as yet to draw conclusions as to permanence of cure. In regard to mode of administration, he preferred infusion to injection. A large-bore needle was not necessary. If the saline solution were freshly made reaction was milder, possibly owing to entire absence of micro-organisms.

Mr. J. E. R. MCDONAGH (London) attributed most of the ill-effects which had been recorded as following the administration of salvarsan to the influence of the spirochætæ themselves, particularly in the nervous system. Accidents also resulted from errors in technique and probably also in connexion with an arsenic idiosyncrasy which could not be

anticipated. Optic neuritis and affection of the cochlear nerve occurred in the second stage as part of the original disease, and indicated rather that the treatment had been inadequate. He considered neither of these nerve conditions a contra-indication to the use of salvarsan. After administration there was a rise of blood pressure, succeeded by a fall, attributable to the alkaline solution. This was important in connexion with diseased conditions of the heart and large vessels. Preparation of the patient should be in all respects the same as for other operations, especially as regards preliminary rest, relative starvation, and clearing of the bowels. When vital parts were involved in the disease the local reaction might have very serious effects, such as meningitis or hæmorrhage in various directions. The solution employed should be neutral in reaction and the dose 0·6 gramme salvarsan in 10-ounce saline solution. He advised treating cases in the earliest stage, repeating the injection in 14 days and continuing with intramuscular injections of mercury, many recurrences being due to auto-infection.

Dr. R. SCHUSTER (Aachen) contended that the Wassermann reaction was reliable either in the latent or active stage of syphilis. In latent and parasyphilitic conditions salvarsan was quicker and also more dangerous in its effects. He referred to cases of locomotor ataxia in Westphalia which had died suddenly from respiratory paralysis and hæmorrhage in the medulla oblongata. Ordinary treatment commonly failed because it was not persisted in till the cure was completed.

Dr. R. STOPFORD TAYLOR (Liverpool) reported a series of cases treated by salvarsan. General paralysis had not been benefited, but a bad case of locomotor ataxia had been able to walk after 48 hours. The arsenic was rapidly eliminated when given intravenously, and could not be found in the urine after 9 to 10 days. After intramuscular injection, however, it could be detected after several weeks. Disappearance of pain was very striking, as was also improvement in the general health and increase in weight.

Dr. OTTO F. F. GRÜNBAUM (London) said that in tabes dorsalis it was too much to expect formation of new tissue, but arrest of the disease and cessation of pain might be secured. Freshly prepared saline solution and a minimum alkalinity were important. A slight addition of acid could be made without causing a precipitate. A small needle could be used provided it could be kept free of clot. If the vein was small, freezing to the skin made transfixion easier. A second injection could be safely undertaken after 48 hours.

Dr. G. PERNET (London), Dr. G. H. LANCASHIRE (Manchester), and Dr. J. C. MCWALTER (Dublin) also spoke before Mr. LANE and Captain HARRISON replied.

TROPICAL MEDICINE.

THURSDAY, JULY 27TH.

President, Sir FRANCIS LOVELL, K.C.M.G. (London).

At the opening of the sitting Dr. A. W. G. BAGSHAWE, director of the London Sleeping Sickness Bureau, made an important announcement regarding

The Most Recent Advance Reported as to Experimental Inoculation of Sleeping Sickness.

He said that Professor F. Kleine, of the German Sleeping Sickness Commission, who had been the first to prove that Trypanosoma gambiense underwent a cycle of development in the body of the Glossina palpalis, and who had been continuing his research work in Africa, but who was at present home on leave in Germany, had sent him a communication in which he said that he had received information by telegram from Dr. M. Taute in the Tanganyika district to the effect that the experiments with the object of transmitting sleeping sickness by the agency of Glossina morsitans had proved successful. Of 16 monkeys experimented upon, six had become infected, the disease having been unquestionably conveyed by G. morsitans. This, said Dr. Bagshawe, was an important discovery, for hitherto they had regarded G. palpalis as the sole agent by which sleeping sickness could be transmitted. That under certain circumstances G. morsitans also could convey the infection served to explain some recent puzzling cases of sleeping sickness which had occurred in Rhodesia and Nyasaland, in districts where, though carefully sought for, no trace of G. palpalis could be found, and where, consequently, the origin of the cases could not be accounted for. They would, however, have to wait for full details of these experiments until the issue in due course of the printed report of the German Commissioners.

Dr. J. W. W. STEPHENS (director of the Incorporated School of Tropical Medicine, Liverpool) then opened a discussion on

Yellow Fever on the West Coast of Africa.

He explained that the duty of opening the discussion had devolved upon him in consequence of the unexpected death of Sir Rubert Boyce, who had already with great vigour and ability dealt with the question. For himself he wished to say that he desired to approach this difficult subject more as a critic of the evidence brought forward in favour of the alleged endemicity of yellow fever on the West Coast of Africa than as a partisan of one side or the other. So far as he could make out, no one denied that the disease did appear now and again in that region. On the one hand, there were those who contended that these cases were due to an imported infection, possibly from South America or the West Indies, brought on board ships; while others maintained that the cases arose from the locality itself where the native acted as a reservoir of the virus. Some persons alleged that the evidence as to transmission of yellow fever by the stegomyia fasciata was not definite or precise, and some suggested that the parasite might be different from that of South America. It had, however, to be admitted that stegomyia abounded in the towns on the West Coast of Africa, but notwithstanding this fact there had not been any recent epidemics of the disease on a large scale in any of these towns. Was this cessation of epidemics to be explained by native insusceptibility, or had the natives acquired immunity by previous mild attacks? It was maintained by some that natives had a natural resistance to yellow fever infection. Such examples of this natural resistance had been met with—e.g., among large bodies of troops in the Mexican war—some corps entirely escaping, while others suffered severely, both parties apparently being subjected to the same opportunities for contracting the infection. With regard to the alleged natural resistance of negroes to yellow fever, in the American war with Cuba it was found that the black troops suffered equally with the Americans. If yellow fever be not imported in each instance into the West African towns, the disease must be endemic, the native acting as the reservoir of the virus. This was the late Sir Rubert Boyce's view. Recent text-books make the statement that yellow fever is endemic in West Africa, and Dr. Stephens said he was not prepared to dissent from that statement. He thought it impossible to believe that the disease could be so frequently imported. Endemicity of yellow fever implied that the infection spread to some extent among the natives, and that this infection resulted in subsequent immunity. It was obvious that more careful investigation on the spot was necessary, and they had therefore to be cautious in drawing too hasty conclusions. Mere assertion on the one hand or a simple denial on the other was useless. Sir Rubert Boyce also believed the bilious remittent fever of West Africa was yellow fever. But the difficulty was in proving the diagnosis, no specific organism of yellow fever having as yet been identified. A practical point in the prevention of yellow fever, if it existed endemically in West Africa, was to secure, in addition to anti-mosquito measures, sufficient isolation of the housing of the European from that of the native community. Further investigation was needed to settle in a satisfactory way whether (1) yellow fever was imported or endemic in West Africa; (2) had the native natural or acquired immunity, and was this the reason the disease did not spread? It was also very important to learn definitely whether bilious remittent fever was being mistaken for yellow fever. Inquiry was necessary before a settlement of the disputed points could be reached.

Dr. W. T. PROUT, C.M.G (Liverpool), reminded the Section that the subject had already been discussed and fully thrashed out at recent meetings of the Society of Tropical Medicine in London, with the assistance of the late Sir Rubert Boyce, and so far as he could see no new facts had been adduced since then. What was needed, he thought, to help to a right decision was the production of more definite facts as to the actual conditions under which alleged yellow fever cases were met with in West Africa. Without doubt cases of true yellow fever occurred now and again on the Coast, but that the disease was always happening not only in a few places but up and down the country, as contended by the late Sir Rubert Boyce, there was no proof at all.

The constitution of the West Coast town population was usually a small isolated community of Europeans and a large community of natives, the Europeans being constantly recruited by non-immunes from home. It was alleged that the native population had acquired immunity, but certain of the West Coast towns had an annual large influx of natives brought from the interior, presumably having no acquired immunity. If the disease were endemic there was material both among Europeans and natives in which it could spread and give rise to an epidemic. Dr. Prout quoted some of his own personal experiences gained while serving in West Africa, and contrasted yellow fever and malaria in their modes of spread. He contended that though occasional cases of yellow fever occurred in that region they were not by any means so common as the late Sir Rubert Boyce asserted. Dr. Prout was not convinced that the disease existed commonly in a mild form among the natives of West Africa, thus conferring subsequent immunity upon them. But he wished to keep an open mind, and would carefully consider any trustworthy evidence on the subject if it were submitted to him.

Dr. H. SEIDELN (Liverpool, formerly professor of pathology and bacteriology in the University of Merida, Mexico), pointed out that the views put forward by Sir Rubert Boyce were not new, but it had required some courage to bring them up in the face of official disapproval. The conditions of the districts on the West Coast of Africa did not, in his opinion, differ from those found in other centres, as, for example, in South and Central America, where yellow fever was endemic. From what he had heard he believed that in West Africa only severe cases of yellow fever were reported as such, and this did not give a true idea of the extent of the prevalence. Dr. Seideln gave some interesting details of an illness from which he and his family suffered within a month of their arrival in the Mexican province of Yucatan, but which was not at the time diagnosed as yellow fever. From facts which came to his knowledge afterwards he regarded the illness as true yellow fever. As he was exposed subsequently to various opportunities for contracting the disease and escaped, he inferred that the illness in question had conferred immunity upon himself and family. It was significant that the local health officials offered to give him a certificate that he was immune to yellow fever, so that he could travel without any restriction in South and Central America. He believed that the number of stegomyia in West Africa was not large enough to allow of the development of epidemics of yellow fever. Investigation was greatly needed to settle the amount and distribution of the stegomyia fasciata in West Africa, and whether after all this was the transmitter of the yellow fever infection in that region. It was possible that some other insect acted as a carrier of the disease. He disputed the statement that the blood of a yellow fever patient ceased to be infective after three days in all cases, for he had himself met with cases which were infective at a later stage than this. Extremely careful and exact observations were required to settle the question. The biology of the stegomyia should also be investigated, and the clinical diagnosis of yellow fever should be fully worked out. Dr. Seideln said that he had done some research work on yellow fever which he proposed shortly to publish.

Dr. A. J. CHALMERS (Colombo) continued the discussion, mentioning his personal experiences while stationed in West Africa. As regards bilious remittent fever, there were some cases in which examination of the blood revealed evidence of malarial parasites, but in others with similar symptoms no such evidence was forthcoming. He was unable to say that the latter were instances of yellow fever. He was disposed, however, to believe that yellow fever was endemic in West Africa.

Major R. W. H. JACKSON, R.A.M.C. (Plymouth), referred to the outbreak of yellow fever during the Ashanti war in 1872 and his personal experiences in West Africa and the West Indies. He regarded the quarantine regulations in the West Indies as very effective, but it was very necessary that the diagnosis of yellow fever should be beyond dispute before they were applied.

Dr. R. H. KENNAN (Dublin) also related some personal experiences while stationed on the West Coast of Africa. Cases he did not diagnose as yellow fever at the time now appeared to him to have been instances of yellow fever. He thought that the disease went in cycles, appearing epidemically in some part of the coast every eight years.

Dr. J. W. MARTIN (Dumfries) doubted that yellow fever was always present in West Africa. He admitted the difficulties of diagnosis, especially in mild or anomalous cases. Until some method for establishing the diagnosis of the disease was found, he feared we must remain in doubt as to the alleged frequency of yellow fever in West Africa.

Professor W. J. R. SIMPSON (London) believed that while yellow fever did occur on the West African coast from time to time, it was by no means so frequent as was asserted. Natural immunity was an interesting point. He mentioned an outbreak comprising 46 cases—viz., 27 Europeans, of whom 23 died; 13 natives, of whom 7 died, and 6 Syrians, of whom all died. This outbreak showed that natives were attacked, and that a proportion died from the disease. One might naturally expect that with the large number of Europeans constantly going to West Africa yellow fever, if widely endemic, would attack these non-immunes far more frequently than was actually the case. He thought further investigation on the spot was called for.

Dr. H. P. COLE (Alabama) said that, as one of the officers of the United States Public Health and Marine Hospital Service, he, as well as his colleagues, was always on the look-out for endemic cases of yellow fever among the coloured population, but he had seen none as yet. Bilious remittent fever was not regarded by the Americans as yellow fever.

Dr. M. CAMERON BLAIR (North Nigeria), Dr. G. ROME HALL (London), and Dr. K. S. WISE (British Guiana) also took part in the discussion.

After the PRESIDENT had expressed his opinion that the so-called bilious remittent fever in Sierra Leone, where he had at one time served, was in reality yellow fever,

Dr. STEPHENS replied. He said he was surprised to find that, after all, a majority of the Section regarded yellow fever as endemic in West Africa, but no one had thrown light on the reason why if endemic it did not spread oftener and cause epidemics. He did not commit himself to the opinion that bilious remittent fever was yellow fever, but he thought that a case for inquiry had been made out. The difficulties of the diagnosis were the crux of the whole matter, and no advance could be made until some trustworthy pathological test for yellow fever had been discovered.

Dr. H. BAYON (Craggs Investigator, London School of Tropical Medicine) then read a paper on the

Culture of the Leprosy Bacillus.

He said that Hansen's bacillus was generally regarded as the cause of leprosy, but it was possible that it was merely a harmless accompaniment of the real organism. He referred to the recently published work of Captain T. S. Beauchamp Williams, I.M.S., who had cultivated two types of organism from his cases—(*a*) a diphtheroid non-acid-fast organism, and (*b*) an acid-fast streptothrix. Dr. Bayon then described a number of carefully planned laboratory experiments which he had carried out on animals. His investigations were made partly at the Lister Institute and partly at the London School of Tropical Medicine. His conclusions are summed up by him as follows: 1. It is not sufficient to culture an acid-fast or other organism from one or several cases of human leprosy to enable the statement to be made as to its relation to the disease. This must be the result of complete animal experiments and extensive serological tests. 2. It is possible to culture from cases of human leprosy an acid-resisting diphtheroid which acquires acid-fast properties on being injected into rats or mice. It is possible to regain the germ by cultures from the animals experimented upon as an acid-fast rod. Re-injected into rats or mice it causes the identical changes of spontaneous rat-leprosy and very striking analogous lesions similar to those found in the glands and organs in human leprosy. 3. No special medium can guarantee a culture from a case of leprosy. The growth depends on circumstances which we do not so far exactly know and cannot control. This applies to the lepra bacillus in its acid-fast form. The most favourable media appear to be placental extract-agar and horse serum nutrose-agar, with the addition of 2 per cent. of ground-up smegma bacilli. 4. Agglutination, precipitation, complement deviation, and percutaneous tests can be used to prove the relationship of acid-fast or other germs cultured from cases of leprosy. 5. Serological tests and histological changes taken together seem to prove that rat and human leprosy are caused by the

same germ. It is therefore possible that the disease can be transmitted from rat to man, given an appropriate carrier. As rat-leprosy seems endemic to a slight extent in England this may be an explanation of the cases of leprosy where infection has occurred without the patient ever having been abroad. 6 Nodular and anæsthetic leprosy may very well be due to different modes of infection. 7. Kedrowsky's work on the variable morphology of the lepra bacillus appears to be confirmed by these experiments.

Owing to the lateness of the hour at which Dr. Bayon's paper was read there was no opportunity for discussion, but a demonstration of his microscopical preparations was given by him to those interested in the subject after the sitting had terminated.

THE ANNUAL EXHIBITION.

(*Concluded from p. 389.*)

III.—FOODS AND FOOD PRODUCTS.

THE special foods were worth studying, foods for the diabetic and milk foods being most in evidence. In this section it was apparent again that manufacturers are devoting real scientific attention to the composition of foods with the view of adapting them to special requirements.

Albulactin produced considerable interest at the stall of Messrs. A. Wulfing and Co., of 12, Chenies-street, London, W.C. As we have already pointed out in our analytical columns, this substance represents the true milk albumin, the protein which predominates in human milk. Its addition to diluted and sweetened cow's milk is, as practice has shown, of great advantage in infant feeding. Messrs. A. Wander, Limited, of 1 and 3, Leonard-street, London, E.C., exhibited specimens of "ovaltine," which, as our analysis has shown, presents the elements of a complete food, containing in addition the ovo-lecithin of eggs. It is made with malt extract, milk, eggs, and a cocoa flavouring, and occurs in the form of a granular powder soluble in warm milk or water. Messrs. Southall Brothers and Barclay, Limited, of Lower Priory, Dalton-street, and Dale End, Birmingham, showed in addition to a series of chemical and pharmaceutical preparations a milk food reinforced with glycerophosphates of calcium, magnesium, and sodium known as "vitafer." Mr. Richard Maurice, of Bedford Chambers, Covent-garden, London, W.C., represented Messrs. Brusson Jeune, the makers of the diabetic bread known by their name. It is not claimed that this bread is free from starch—and our analysis has shown that starch is present—but it has been considerably reduced, the amount of protein being proportionately increased. The protein amounts to nearly 40 per cent., while the carbohydrates amount to 50 per cent. An excellent assortment of foods for diabetic and plethoric patients was shown by Messrs. G. Van Abbott and Sons, of Baden-place, Crosby-row, Southwark, S.E. These included gluten bread (starch free), gluten flour, semola, and biscottes. Besides there were table jellies, almond biscuits, bran biscuits, and so on. To emphasise the merits of barley water was the chief object of Messrs. Keen, Robinson, and Co.'s exhibit, of Denmark-street, St. George's-in-the-East, London, E., who showed specimens of Robinson's patent barley and patent groats. In addition there were shown at this stall examples of Colman's medical mustard bran, concentrated mustard oil, and Colman's sinapisms. Messrs. Callard and Co., of 74, Regent-street, are well known for their endeavours to make the diet of the diabetic an agreeable and a scientific one. They showed starchless and sugarless breads, biscuits, cakes, rusks, and sugarless marmalade, jams and jellies, fruits, chocolate, and milk. Messrs. J. Reynolds and Co., Limited, of Albert Flour Mills, Gloucester, showed some admirable specimens of wheatmeal bread, and also various grades of wheats, the whole exhibit affording an excellent object-lesson as to the valuable constituents in flour which should not be eliminated. There was a large selection of active digestive ferments on the stall of Messrs. Armour and Co., of Atlantic House, Holborn-viaduct, London, E.C., besides a series of special foods. Their essence of pepsin, elixir of enzymes, glycerine extract of red bone-marrow, glyco-lecithin, and vigoral, a highly concentrated beef preparation, deserve special mention. Messrs. Savory and Moore, Limited, of 143, New Bond-street, exhibited a number of foods which have enjoyed a well-deserved reputation. Amongst these were peptonised milk preparations, coffee and chocolate, and a useful malted food. Their "new chemical food," or fructole of red bone-marrow and glycerophosphates, is giving excellent results in defective nutrition, anæmia, and so forth. Messrs. Brand and Co., Limited, of Mayfair Works, 74 to 84, South Lambeth-road, Vauxhall, London, S.W., showed their well-known "essences" of beef, mutton, veal, and chicken, which are now put up in glass. There were besides a number of special foods for the invalid, which, apart from nutrient merit, appeal to an indifferent palate. Cerebos salt (Cerebos, Limited, of 3, Maiden-lane, London, E.C.), the pioneer of dry powdery salt which does not cake, exhibited their speciality, while not far away was the stall of Virol, Limited, of 152-166, Old-street, London, E.C., where specimens of virol were shown. There is now abundant practical evidence in favour of the value of this complete food in wasting diseases. It contains marrow fat emulsified with carbohydrates (active malt extract), including red marrow, and phosphates are plentiful. Its special nutritive value has received considerable testimony. An interesting selection of food products and adjuvants was shown by Messrs. Fairchild Brothers and Foster, of 64-65, Holborn-viaduct, London, E.C. There were panopepton containing peptonised lean beef and wheat flour, pepsencia containing the active digestive principles of the gastric juice, lecithin in the forms of elixir and glycerole, the "nerve food," and a number of carefully prepared digestive products known as "pepules."

The food exhibits were of a special rather than of a general kind, and showed in many directions advances on previous attainments.

IV.—SANITARY APPLIANCES.

The exhibition here was small. There was a curious falling off in the number of disinfectant preparations shown. The Jeyes' Sanitary Compounds Company, Limited, of 64, Cannon-street, London, E.C., were represented in a comprehensive series of disinfectant preparations the basis of which is cyllin, an effective bactericide, while it is much less toxic than carbolic acid. A profusion of antiseptic preparations with different active agents to do the work of disinfection was exhibited by the Sanitas Company, Limited, of Locksley-street, Limehouse, London, E. Peroxide of hydrogen, formaldehyde, phenolic fluids (sanitas-bactox, a clear fluid forming a white soapy emulsion with water, and sanitas-sypol, a clear soapy fluid which forms a clear mixture with water), sanitas (oxygenised turpentine) sulphur candles, and so forth, made up a stall crowded with sanitary appliances. Messrs. Slack and Brownlow, of Abbey Hey, Gorton, Manchester, showed several models of their simple and effective germ-proof filter made for high and low pressure. There were also shown a hospital filter made for dealing with hot and cold water for use in the operating theatre, and a "sanitary bulb" for automatically diffusing disinfectant into the water of the flushing tank. Close by were specimens of flooring polished with the sanitary paste, ronuk, of Ronuk, Limited, of 16, South Molton-street, London, W. Ronuk is obviously an application which conduces to a sanitary environment. It is used on hospital floors with marked success.

V.—MINERAL WATERS, BEVERAGES, ETC.

A feature of this section in previous years has been the demonstration by photographs, literature, &c., of the merits of certain of our leading watering places. There were but a few represented on this occasion. The brine baths of Droitwich, which enjoy a deserved reputation in the treatment of rheumatic affections, found illustration at one stall, and stress was laid upon the advantages which this place offers to those who seek a nerve- and rest-cure. Buxton was also represented in a series of photographs which sufficed to show how alive to the modern requirements of a spa the authorities at this health station are. The exhibit was under the direction of Mr. F. J. C. Broome, the manager. The Apollinaris Company, Limited, of 4, Stratford-place, Oxford-street, London, W., exhibited samples of their well-known natural bitter saline purgative water, Apenta, the action of which is due chiefly to the sulphates of magnesia and soda present, but carbonate of sodium is an important constituent, giving the water a soothing effect upon the lining of the stomach and bowel. There were also examples of Apollinaris, a really alkaline table water and antacid; and Johannis water, with and without lithia. Messrs. Ingram and Royle, of 45, Belvedere-road, London, S.E., had a quite exhaustive series of mineral waters on their stall. There were the Carlsbad waters, Carlsbad sprudel salt (evaporated from the spring itself),

Vichy water, Contrexéville, Friedrichshall (saline aperient), Giesshübler (a clean alkaline table water), and Hunyadi Janos (a bitter purgative saline water from the famous springs near Budapest). Friedrichshall water was also represented at the exhibit of Messrs. C. Oppel and Co., of 10 and 12, Milton-street, London, E.C. In addition to the sulphates of magnesium and sodium it contains relatively large amounts of the chlorides of sodium and magnesium, which render the water alterative and an aid in metabolism.

VI.—PUBLICATIONS.

There was an interesting collection of modern medical works to be found on the stalls of several well-known publishers. Amongst the publishers represented were: Messrs. Iliffe and Sons, Limited, of London and Coventry, the proprietors of *The Autocar*, which provides information and advice to medical men in regard to the use of motor-cars; the Oxford Medical Publications (Henry Frowde); Messrs. Macmillan and Co.; Messrs. Rebman, Limited; Mr. E. A. Brooke Williams; Mr. H. K. Lewis; Messrs. John Wright and Sons, Limited; the W. B. Saunders Company; and Messrs. J. and A. Churchill.

VII.—MISCELLANEOUS.

Amongst the miscellaneous exhibits worth recording was the gas-heating apparatus of Messrs. John Wright and Co., of 19 and 21, Queen Victoria-street, London, E.C., who showed the "Eureka" gas fire fitted with a patent thermo fire-front with a big radiating surface, and a gas-heated boiler in which the consumption of gas is controlled by an automatic valve which enables the water to be heated and kept hot with a small amount of gas. The underclothing material known as "Aertex cellular," shown by the Cellular Clothing Company, of 72 and 73, Fore-street, London, E.C., also made an interesting exhibit. The material is comfortable and light whilst sufficiently protective to the body. A specially dyed red Aertex fabric was shown for tropical use, the view being that such a material cuts off the greater part, at all events, of the actinic rays of the sun.

BRITISH PHARMACEUTICAL CONFERENCE.

THE PRACTICE SECTION.

THE newly constituted Practice Section of the British Pharmaceutical Conference has held its first meeting at Portsmouth in connexion with the Conference whose proceedings we briefly noted the week before last. Until this year the Conference has devoted itself almost entirely to scientific matters, but a large number of members having expressed the desire that the scope of the work should be enlarged so as to embrace subjects of more general pharmaceutical interest, the rules of the Conference were altered to permit of the inauguration of the new section. Accordingly, in addition to the papers read in the Science Section, abstracts of which have already appeared in THE LANCET,[1] subjects of a non-technical character were discussed at the forty-eighth annual meeting.

Mr. J. C. UMNEY presided, and the first subject considered was that of Secret and Proprietary Medicines. Recently the Conference caused an inquiry to be made among over a hundred local pharmaceutical associations in the United Kingdom with the object of ascertaining the views of pharmacists regarding the sale of these articles. The result of this inquiry was announced by Mr. E. S. PECK, one of the honorary secretaries of the Conference. It appears that the sale of proprietary remedies is considerable in all districts, and, according to replies received, proprietary remedies are ordered by medical practitioners in many localities. Replies to the various questions were received from 103 associations. To the question, "Are the proprietary articles which are ordered by prescriptions, usually single substances made up by a patent process, or under a protected name—e.g., veronal, stovaine, &c.—or mixtures which any competent pharmacist might be supposed to be able to prepare if the formula were known"? the replies were: Single substances, 6 per cent.; mixtures, 6 per cent.; both single substances and mixtures, 84 per cent.; neutral, 4 per cent. The replies to other questions indicate that the majority of pharmacists would welcome legislation requiring manufacturers to declare the principal ingredients of proprietary remedies, and that a large body of opinion is in favour of joint action being taken by medical and pharmaceutical bodies to bring about a more satisfactory state of affairs. The result of this inquiry having been explained, a discussion was opened by Mr. E. F. HARRISON. Describing various kinds of proprietary remedies, some good and some very bad, he said a strong case could be made out for certain classes of remedies, as, for instance, such as are not of secret composition; if a man by his special experience discovered some new way of combining certain medicines of known value so that their efficiency is increased he was entitled to profit by his special knowledge. He expressed the opinion that legislation should be introduced to make it impossible for fraudulent quack medicines to be sold, and suggested that it would be enough to require the declaration on the label of the names of all the principal ingredients and the exact quantities of any coming within the poison schedule or possessing great activity. He thought the proprietor might be allowed to keep to himself the nature of subsidiary ingredients used, for example, as emulsifying or flavouring agents, and the exact proportions in which the different constituents were combined. For several reasons he thought any legislation on this subject should be preceded by a thorough public inquiry. The discussion was continued by a number of speakers. Mr. J. C. UMNEY, who is chairman of the Proprietary Articles Section of the London Chamber of Commerce and chairman of the Proprietary Articles Trade Association, said that so far as he could find out the bulk of the proprietors of proprietary medicines would be willing to give a certificate of a negative character stating that their preparations do not contain noxious ingredients. Mr. R. A. ROBINSON, an ex-president of the Pharmaceutical Society and a former chairman of the London County Council, considered the retailing of articles for which extravagant claims were made was an illegitimate form of pharmacy. The SECRETARY of the National Food Reform Association expressed the hope that before long the Government would find time to take up the question. On the motion of Mr. HARRISON, seconded by Mr. WIPPELL GADD, a proposition was carried unanimously, calling upon the Government to institute a public inquiry into the advertising and sale of proprietary secret remedies and the law relating thereto with a view to further legislation for the prevention of fraud and quackery.

In the same Section a paper was read by Dr. F. BEDDOW, Vice-Principal of the Portsmouth Technical College, on the Education of the Pharmacist from the Point of View of the Teacher. In his view the present system of educating the pharmacist is by no means an ideal one, and he hoped that when changes were introduced the education of the student would be considered as the important thing and the examination as of secondary importance, and that regulations would be made ensuring that successful candidates shall have received such education as can be obtained without excessive cost to themselves. He hoped the present system of testing candidates by oral and practical examination would be retained and that the written examination and the production of notebooks would be looked upon as an additional help in deciding the candidate's qualification. A discussion followed the reading of the paper.

The National Insurance Bill was then considered and a resolution was carried expressing approval of certain recommendations passed at a special meeting of the Joint Standing Committee of the British Medical Association and the British Pharmaceutical Conference. These recommendations, which were not all confirmed by the British Medical Association, were to the following effect: (1) That the principle be affirmed that the dispensing under the proposed scheme be done through the channels provided by the Pharmacy Acts, and that provision should be made in the Bill for the carrying out of the Chancellor's expressed intention that this work should be done by pharmacists; (2) that insured persons should be allowed free choice of pharmacists; and (3) that provision should be made for exclusion from medical and maternity benefits of persons whose average income from all sources exceeds £2 a week. The principles of the first two of these recommendations were embodied in Clause 14 of the National Insurance Bill during the Committee stage in the House of Commons last week.

At the concluding session of the Conference on July 27th Sir Edward Evans was elected President for 1911–12, and an invitation to hold the next annual meeting in Edinburgh was accepted.

[1] THE LANCET, July 29th, 1911, p. 319.

THE LANCET.

LONDON: SATURDAY, AUGUST 12, 1911.

The Cholera.

In another column a valued correspondent deals in a suggestive manner with the present situation of cholera in Europe, while our correspondent in New York draws attention to the apprehensions in the United States. The fears, freely expressed by numerous epidemiologists at the close of last year, that a recrudescence of cholera would be seen in Europe during the present summer, and that the disease would again become epidemic, have unhappily been realised. Cholera already appears to be extending from two chief centres—Italy and Turkey—and is now threatening a number of countries into which the infection has been imported. Our readers will remember that the epidemic which prevailed in Italy last year subsided about January of the present year, the last cases being notified at Taranto in the extreme south of the Italian peninsula. Nothing more was heard of the disease until early in June, when almost simultaneously announcements appeared that cholera was epidemic in certain places which had last year suffered severely from its ravages, including Naples and Palermo, with their adjoining districts. Up to the middle of July upwards of 1400 cases have been officially notified in a period of about five weeks. So far as can be judged by the published figures the virulence of the existing strain of the cholera organism in Italy is not great, the recorded case mortality rate being a little less than 31 per cent. More recently extensions of the infection have occurred in Northern Italy, groups of cases having been reported in the province of Genoa at Spezzia and elsewhere, and at Leghorn on the coast of Tuscany. In some other districts "cholerine" is said to be prevalent, and there is some suggestion that certain outbreaks of so-called "typhoid fever" are in reality manifestations of cholera infection. Naturally some alarm has been created, and one result has been the postponement until next April of the meeting of the International Congress on Tuberculosis, which was to have been held at Rome in September. Correspondents in the continental press allege that the true incidence of cholera in Italy is not recorded in the returns published by the Italian Government, and that the occurrence of outbreaks is being concealed by the authorities in order that foreign visitors may not be frightened away. The statement is also made in the continental papers that as many as 200 cholera cases have occurred in quite a short period at Venice, and a number of others at Rome, without either of these towns appearing in the official list of infected places, and further, that no notification of these cases in Rome and Venice has been made to the European Powers as required by the terms of the Paris Convention. It is asserted that the policy of concealment practised at Naples last year is being repeated at the present time at other infected towns. How much truth there is in these allegations we are not in a position at present to say, but the suggestion is a very serious one and demands immediate attention.

From Italy cholera has been carried into France, a group of cases having occurred at Marseilles, and also into certain districts in Austria, including Trieste, Gratz, and Cattaro in Dalmatia on the eastern shore of the Adriatic, the source in each instance being traced to some Italian infected district. In some cases we hear that the eating of infected oysters or other shellfish by tourists in certain infected localities in Italy had resulted in attacks of cholera. On shipboard the disease has been carried from Naples and Palermo by Italian emigrants to the United States of America, 25 cases having already occurred in connexion with the port of New York and one at Boston. Some of the attacks occurred during the voyage across the Atlantic, others after arrival at the quarantine station when the passengers were undergoing five days' observation, while yet others occurred after the termination of the detention period in quarantine and after the passengers had proceeded to their destinations. These occurrences have given serious cause for alarm to the American port sanitary officers, who say that while it is comparatively an easy task to prevent the entrance into the States of persons ill with cholera, it is far more difficult to deal with cholera bacilli carriers who are themselves on arrival apparently in good health. On the advice of its medical experts the Government of the United States has issued a fresh order to the national, State and local quarantine officers, collectors of customs, shipowners, and agents, and to all others whom it may concern, that, with a view to diminish the danger from bacilli carriers, steerage passengers from ports or places infected by cholera shall be detained for ten days for observation, unless after five days (the previous period of detention) they are found not to be bacilli carriers. The importation of food by the arriving Italian emigrants was also forbidden. These new measures, however, in less than a fortnight were supplemented by another order, dated July 19th, providing that all steerage passengers arriving at ports in the United States from infected places shall be subjected to a bacteriological examination, and shall not be admitted to entry into the States until it has been determined by this examination that they are not carriers of the cholera bacillus. It is obvious that these new regulations, necessitating as they do bacteriological examination of the fæces of large numbers of persons, will entail a considerable amount of additional work upon the staff of the State and port authorities. In our opinion, it would be very difficult to carry out such systematic examination at English ports. It is not denied that much more care is necessary in America than with us in England to prevent danger arising from the introduction of cholera germs into a country where it is admitted frankly that sanitary circumstances and administration generally are not so satisfactory as with us, and where in some places particularly the public water-supplies have not been sufficiently safeguarded or protected from excremental pollution. These extra precautions now enforced in America may be regarded as the penalty paid for postponing necessary sanitary reforms until danger has actually arisen.

In Turkey, the second centre of diffusion of the cholera infection, the disease has of late been extremely prevalent in

parts of Asia Minor, especially in Smyrna and Samsun and in the districts along the southern shores of the Black Sea. In Constantinople cases have been occurring, sporadically, it is said, but here, as elsewhere in Turkey, the authorities for their own purposes have minimised the outbreak. There is evidence that the infection is spreading in the Turkish provinces; an outbreak is now reported among the soldiers on service in the disturbed districts of Upper Albania. From Turkey cholera has been conveyed into Greece and Bulgaria, and perhaps also into Roumania, but this as yet lacks confirmation. It is somewhat strange that so little has been heard of cholera this year from Russia, where for three years in succession the malady has been widely epidemic and where in 1910 no fewer than 216,000 cases were reported with 101,000 deaths. Scattered groups of cases have, however, been already reported in June or July in the basin of the Volga in the governments of Kazan, Samara, and Astrachan; in Southern Russia at certain Black Sea ports in the governments of Kherson and Ekaterinoslav, and at Baku on the Caspian Sea. There is an entire absence of mention of cholera at St. Petersburg which has usually in past years suffered severely; it is possible that this present immunity may be due to the measures recently taken to "sterilise" the water for the city's public supply taken from the polluted River Neva. It is said that now first of all the water is clarified by the addition of sulphate of aluminium, then sent through rapid filters and afterwards passed to the "sterilising" towers, where it is mixed with ozonised air by means of Otto injectors. In Western Russia a few cases have been notified in the government of Minsk, which is near the borders of Poland, and at least one fatal case has occurred in Vitebsk on a raft coming down the river Dwina (or Düna), which is navigable for upwards of 400 miles of its course, and which flows into the Baltic Sea at Riga. It has generally in former years been the Baltic ports which were regarded as the greatest source of danger from cholera to this country. Up to the time of writing there is no indication of any present danger from that quarter. Should cholera invade the Baltic ports in August or September less danger is to be apprehended than if they had become infected earlier in the year, as there would be less time for the epidemic to develop before the advent of the colder weather, when commonly the infection spontaneously subsides. But in England we place our reliance mainly in the excellence of our sanitation and administration to protect us from the dangers which chance importation of cholera infection might bring to us, as we have pointed out on many previous occasions in these columns.

The National Insurance Bill.

ON Friday in last week the Chancellor of the Exchequer briefly reviewed what had been done in Committee of the House of Commons in respect of the National Insurance Bill, and while he drew attention to points of difficulty ahead, he congratulated the House upon having made very substantial progress. As far as the profession of medicine is concerned—and on every side of this far-reaching measure we find medicine directly or indirectly affected—the clauses of the Bill as amended in Committee, though not escaping criticism, have been received by our readers with satisfaction. Dr. CHRISTOPHER ADDISON'S valuable amendment, by which the administration of medical benefits was transferred to the Local Health Committees, has naturally called forth a protest from the Friendly Societies. The President of the National Conference of Friendly Societies, a body which is said to represent a membership of 6,000,000, with funds of £40,000,000, is quoted in the press as saying that there is considerable dissatisfaction throughout the Kingdom in consequence of the amendment, "whereby a plan which had resulted in an amicable understanding between Friendly Societies and their medical men was taken away." The President of the National Conference of Friendly Societies has been living, it would seem, in a fools' paradise if he really believes that the relations between the medical profession and the Friendly Societies have hitherto been cordial. While we grant now, as we have done often in our columns, that in some instances the medical officer to clubs and medical aid associations has been properly treated, the evidence has always been overwhelming that such cases were the exception and not the rule. Our columns have over and over again described the distressing circumstances which marked contract medical work done under the auspices of medical aid associations, and the wish was unanimous in the medical profession to be free from the control for the future of the Friendly Societies in the matter of the distribution of medical benefits. We have no doubt whatever, as the President of the National Conference of Friendly Societies is reported to have said to a representative of the *Daily Telegraph*, that the societies would have been prepared, if the discretion had been left with them, to increase the allowances made to their medical officers; they must have been only too well aware that no other course was open to them. But the medical profession has felt all along that in the hands of the societies their interests were not safe; in the past the complaints of the medical officers of the societies were too often not attended to; their professional position was not recognised; their efforts to obtain adequate remuneration even met with determined resistance. If those favourable concessions, which we now learn that the Friendly Societies would have been willing to make under the Bill, had been spontaneously offered, or had been granted years ago in response to the numerous protests of their medical officers, the public would be more ready to see the objections which are seen by the Friendly Societies to Clause 13 as now amended. But with full experience of what the relations between Friendly Societies and their medical officers have been in the past we rejoice at the transfer of the distribution of medical benefits to the Local Health Committees.

Clause 14 as amended may on reflection, we think, be considered, as we termed it last week, a medical triumph. We admit to the full the simplicity and advantage of a wage limit, but we have never been able to shut our eyes to the fact that the arguments which would be brought forward against such a proposal in the House of Commons would inevitably prevail. The process of ascertaining whether the wage limit had or had not in any individual instance been exceeded would be difficult and vexatious; employment, though much better than heretofore, and though never so

precarious in the upper grades of labour as in the lower, is still an uncertain thing, and many of the insured persons will hardly know exactly what their average incomes are; lastly, the conditions of employment in different centres, and in town and country, vary so largely that a man making on an average £75 a year in one place may be substantially richer than a man making £104 in another. Of course the agreement of the House of Commons to the clause definitely committed the medical profession to a form of contract practice, but it would seem that a majority of our readers are reconciled to this principle, so long as safeguards can be maintained against any oppressive methods of its application. The position will now be fair or unfair to the medical profession according as the Local Health Committees are able to make adequate arrangements with the medical profession, and Dr. ADDISON'S admirable amendment securing local option in respect of contracts ought to fulfil his expectations as set out in our Parliamentary report. The Local Health Committees are to be appointed with the approval or at the instance of the Insurance Commissioners (one of whom is to be a medical practitioner) by the county councils, the county borough, and the contributors, and upon these bodies the local sanitary authorities and the medical profession will be represented. The county medical officer of health will attend the meetings. In these circumstances it seems to us that our position should be safe. Resistance to the legitimate recognition of those upon whom, after all, depends the whole working activity of the Bill has been sufficiently demonstrated in the House of Commons during the recent discussions in Committee to be small and factious. We have ourselves always believed that the people of this country, a country which has stood in the van of civilisation by reason of its splendid charities and its organised sanitary service, probably desired efficient medical service, and therefore would be willing to grant the necessary facilities for obtaining it. Undoubtedly difficulties may yet arise between the Local Health Committees and the local medical profession, but in our view the present attitude of the public towards the medical profession is a warrant for the belief that in questions of dispute we shall get a fair hearing. The desire of the Local Health Committees will be to ensure the public health of the local communities.

There is still considerable anxiety felt with regard to the position of the voluntary hospitals under the Bill. The belief is general that the out-patient departments will be relieved, but that any benefit that may accrue to the hospitals in this manner will be lost by an increased pressure upon the in-patient department. Hopeful people see in the measure a promise of the introduction of order into the dispensation of medical charity. Less cheerful people fear lest the voluntary subscriptions to hospitals, both of employer and employed, should fall off when compulsory payments to invalidity insurance begin. If the hospitals had been placed in the same position as sanatoriums with regard to sick benefits their pecuniary position would be less anxious, but the control of the Local Health Committees, which would have followed, might have been very difficult to carry into effect. The obvious method of preventing the waste of labour that takes place in the out-patient departments of voluntary hospitals, and at the same time of dealing with the curse of hospital abuse, is to bring the out-patient departments of the hospitals into touch with the work of the general practitioner, the out-patient departments being used mainly in a consultative capacity. Before the vast scheme of the National Insurance Bill was outlined the suggestion made by most who gave heed to a very difficult situation was the development of provident dispensaries, whereby these institutions would become sorting-houses for the out-patient departments. Under this idea, through the machinery of the dispensaries those patients could be ascertained who could not pay adequate fees. The medical officers of the dispensaries would recommend to the hospitals the suitable cases for treatment, and in this way the hospitals would be supplied with the proper scientific cases without having their charity abused, while quite poor patients would obtain the advantages of coöperation in medical treatment. If the Local Health Committees were placed in a position to subsidise the hospitals they would form a direct link between private contract practice and the out-patient departments of the great charities; but we think that in any event the work of these bodies must have an enormous effect in the near future on our national health.

Annotations.

"Ne quid nimis."

THE WEATHER OF JULY.

FOR several years the summers in this country have been both too cold and too wet. The farmer has also sometimes had occasion to deplore the persistent rain and the lack of seasonable heat. This year it is possible that the mischief resulting from the lack of rain has been almost, if not quite, equal to that caused by the gloom and wet of the few summers preceding. The wind direction on which the temperature at all times of the year so much depends was generally favourable for warmth. As a rule, it came from a southerly point of the compass, often from south-east. Reaching this country from the heated continent after such a short sea passage as the English Channel the air was perceptibly warmer than usual on its arrival. If it had come from the westward after a long passage over the relatively cold waters of the Atlantic the sunshine in these islands would hardly have raised its temperature to 90°, except perhaps in East Anglia. In this country great summer heat which is at all permanent is dependent on two principal factors. The barometer must be high, or rather so, and uniform over a wide area, so that the flow of air from whatever quarter may be light; and the sky must be sufficiently denuded of cloud to allow much sunshine. However high the temperature may be it begins to fall soon after the wind becomes really strong—i.e., a steady flow of air at the rate of upwards of 25 miles an hour—and great heat is never maintained for more than a day or so with an overcast sky. The weather of July was dry in all parts of the kingdom, but the duration of the drought was much longer in the south-eastern and southern counties of England than elsewhere. Over a large area in those districts the drought, according to Dr. Mill, the well-known rainfall authority, was the most severe, taking the extremely high temperature into consideration, of which there is any record. Longer droughts have been experienced, but in the present case the 25 rainless days were nearly all abnormally hot, and the humidity of the

atmosphere always very slight. The effect of the drought on the soil was consequently aggravated very considerably. London, at all events the central portion of it, is generally the most torrid spot in the kingdom during a spell of hot summer sunshine, and it was so on the majority of the days of last month. Occasionally, however, the temperature in other parts of south-eastern England was quite as high, notably at Margate. That resort, while it is much cooler than London and its vicinity during bright weather with the wind from some northerly or easterly point of the compass, is, in common with the other resorts facing the North Sea, very hot whenever there is much sunshine accompanied by a gentle flow of air from the south-west or west. London and its suburbs may be taken as representing fairly the average temperature in the home counties and south midlands, and the figures below show the means both of the maximum and minimum reading for the month, and also the mean temperature of the month, with the difference from the average at the various stations in the metropolitan area :—

	Mean maximum.	Mean minimum.	Mean temperature.	Difference from average.
Kew	79° ...	56° ...	67·6° ...	+4·8°
Greenwich ...	81 ...	55 ...	68·3 ...	+4·6
Hampstead ...	77 ...	57 ...	66·7 ...	?
Westminster ...	79 ...	58 ...	68·6 ...	+4·7

It will be seen that in spite of the high mean of the maximum the difference of the mean temperature from the average of the month was not particularly large—less than 5° at all the stations. This is explained by the fact that the minimum temperature of the nights was often very little above the average. Considering the great heat of the afternoons the nights were relatively cool, the thermometer more frequently falling to below 60° than remaining above it. Westminster was, as would be expected, warmer at night than the outlying places, while during the afternoons elevated Hampstead was the coolest spot. The highest reading recorded was 96° on the 22nd, Greenwich and Westminster both having the same degree of heat, while at Hampstead the thermometer touched 92°, and at Kew 89°. At Greenwich there were as many as 18 days with a temperature above 80°, but at Hampstead there were only 9, at Kew 12, and at Westminster 15. It is very seldom that these islands enjoy as much sunshine as countries in the same latitude on the Continent, and it is probably true that it would be beneficial both to the public health and to agriculture if they had more. But last month, at all events, there was enough and to spare. In many parts of southern and eastern England a new record was established, a record which is not likely to be broken for a generation. At several of the resorts the total number of hours was about 380, or at least 12 hours a day, this high figure being recorded in various places between the coast of Kent and Torquay. Along the west coast the figure was more moderate, but as far north as Llandudno there was a mean of nine hours a day. London's allowance was lower than that of the south coast, but was nevertheless a record, and was about three hours a day above the normal. At Kew the figure equalled 336 hours and at Greenwich 334 hours, while at Hampstead it was 329 hours, at Westminster 319 hours, and in the City 300 hours. An average of nearly nine hours a day for the City is extremely high. During July of last year there were only 94 hours and only 102 hours at Westminster, while at Greenwich and Kew the respective figures were 113 and 111 hours. Throughout France and Germany, and also in the Netherlands and at times in Switzerland, the heat was generally greater than in this country, and the drought was also very pronounced. At Paris the mean maximum temperature was as high as 83° and the total number of hours of sunshine 357.

A NEW SIGN OF ACUTE INTESTINAL OBSTRUCTION.

IN the *Journal of the American Medical Association* of June 17th Dr. H. G. Watson has described a new sign of acute intestinal obstruction, or rather a modification of an old sign, which promises to prove useful in early diagnosis. Fæcal vomiting is one of the cardinal signs of intestinal obstruction, but when the practitioner is called to a case there may be no vomiting, or if there has been vomiting the vomit may have been thrown away without its characters having been noted. The following case led Dr. Watson to suggest a new method of ascertaining the condition of the stomach contents. A married woman, aged 45 years, had undergone an abdominal operation for some pelvic inflammation 12 years previously. It was necessary to use a drainage-tube for several weeks. Subsequently she enjoyed perfect health. One Sunday evening, after eating a good dinner, she felt so nauseated and distended with gas that she took two enemas, with good results. But the abdominal pain increased and she began to vomit. At 11 P.M. her medical attendant was called and treated her for acute indigestion. On Monday she was no better, and on Tuesday she was worse. Dr. Watson saw her on Wednesday. She was in good condition; the temperature was 99° F., the respirations were 30, and the pulse was 100. The diagnosis was still acute indigestion. She complained of considerable abdominal pain and her abdomen was so distended that she said she could hardly breathe. She had vomited, but none of the vomit was saved. As far as her medical attendant and nurse knew there had been no fæcal vomiting, and the stomach was thought to be empty. On examination a splashing sound was obtained down to the pubes. Acute dilatation of the stomach was diagnosed. Dr. Watson passed a stomach-tube and to his surprise expressed over two quarts of dark brown fluid with a fæcal odour. On examination the fluid proved to be fæcal. Acute intestinal obstruction was then diagnosed. Laparotomy was performed and the ileum was found strangulated by a small band of adhesions. The intestines were much distended and it was difficult to relieve this condition in consequence of many adhesions due to the previous operation. Recovery rapidly ensued. Dr. Watson suggests that as an aid to diagnosis in acute abdominal disorders the stomach-pump should be passed from hour to hour and the contents carefully examined. If these are of a dark brown colour with a fæcal odour acute intestinal obstruction may be diagnosed. Dr. Watson thinks that by this means early diagnosis would be facilitated.

A VILLAGE SANATORIUM.

WE have received a copy of a brochure by Mr. H. G. Richter, a French architect, entitled "Contribution à l'Étude des Sanatoria Populaires—le Village Sanatorium." The preface has been written by the Countess of Aberdeen. After a brief review of the principal varieties of sanatoriums now in existence, the author sets forth his views as to the most desirable form which such an institution should take. He considers that it should be built as a small village in which the patients should be encouraged to perform suitable labour. He does not consider manual work absolutely necessary, but after reading a description of the method of treatment adopted at the Brompton Hospital Sanatorium at Frimley he considers that the patients would benefit by performing graduated labour of a kind useful to village life. His chief contention is that anything in the way of a hospital, both as regards building and daily life, should be completely eliminated. He advises that the buildings should not be of a permanent character, but so constructed that

they can be destroyed at a period to be settled by consultation between the physician in charge and the architect. He lays stress on the good psychical effect which such an institution would have on the patients; it would prove, he says, that they are not dependent upon hospitals; it would give them confidence that "cure" is likely to follow, and it would restore hope that they need not always be useless individuals. Mr. Richter gives details of the "village" which he has planned. It would accommodate 300 patients, with the necessary medical and administrative staff. From an architectural point of view the proposed plan is to be commended; the difficulty would naturally be with the selection of suitable cases. That certain patients obtain much benefit by sanatorium treatment combined with suitable exercise and manual labour has been definitely proved, but the application of this method necessarily has its limitations. For selected patients Mr. Richter's village would undoubtedly be of great service.

HODGKIN'S DISEASE.

THE nature and pathology of the condition to which the name of Hodgkin's disease is usually applied have always been matters of controversy, and the numerous alternative names which have been given to it, such as lymph-adenoma, *adénie*, pseudoleukæmia, lymphomatosis, malignant lymphoma, and malignant aleukæmic lympho-adenoma, bear witness to this. Recent histological and other observations upon the tissues in this disease have, however, at last served to establish its identity as a separate condition, although the actual exciting agent has so far not been recognised. An interesting and exhaustive monograph upon this disease has recently been published by Dr. Kurt Ziegler[1] of Breslau, which should be of special value, since not only is the literature of the subject most carefully reviewed, but the clinical and pathological features are described in detail upon the basis of personal observation of over 70 cases, 16 being confirmed by necropsy, while in 40 the nature was established by the microscopical examination of a gland excised for this purpose. At different times and by different authors the disease has been regarded as neoplastic in character, as an inflammatory affection, and as a condition allied to leukæmia. Dr. Ziegler maintains that there can no longer be any doubt that Hodgkin's disease is a specific inflammatory granulomatous affection, and that although the exciting cause is as yet undiscovered it is specific. Its special peculiarity is its predilection for the lymphatic tissues at first, which though not absolute is very nearly so, in spite of the fact that its secondary manifestations may be very widespread. It is convenient to recognise two stages in this affection—the first or local stage, and the second or stage of generalisation. An analysis of 120 cases showed that the glands in front of and behind the sternomastoid muscle were first affected in 50 per cent., the supraclavicular glands and those at the angle of the jaw in 6 per cent., the axillary in 10 per cent, the spleen in 9 per cent., the mediastinal and inguinal glands each in 3 per cent., while in 12 per cent. no glands were discoverable on external examination. The first or local stage is very variable in duration and may last weeks, months, or years. When the stage of generalisation is reached, the swelling of the glands becomes widespread. The spleen is enlarged in 65 to 70 per cent. of the cases, and the liver in 60 per cent. Pressure symptoms from the enlarged glands are very common, and cachexia, anæmia, and fever, as a rule, supervene. The blood changes are usually of the character of the secondary anæmias. The number of red corpuscles may only be slightly reduced, or may sink to 1,000,000 per cubic millimetre. The blood-platelets are usually increased; the leucocyte count is variable. It may be considerably increased, and there may be a neutrophile leucocytosis. On the other hand, there may be an actual diminution in the number. There is usually a moderate increase in the eosinophiles and in the large mononuclear cells, while the number of lymphocytes is, as a rule, diminished. The duration of the disease in Dr. Ziegler's cases was longer than a year in less than 50 per cent., while in 18 per cent. it was three months or less. He recognises a number of different clinical types—viz., an acute form, localised and general forms, a type with the clinical characters of a mediastinal tumour, a typhoid form, in which the manifestations are very similar to those of enteric fever, a splenomegalic type, and a form with ostitic and periostitic characters somewhat resembling multiple myeloma. Other less clearly differentiated varieties are an intestinal type, Mikulicz's disease with symmetrical swelling of the lacrymal and salivary glands, and a form simulating mycosis fungoides. The histological changes are described as being so characteristic as to confirm their specific origin. The special features consist in the proliferative character of the inflammatory processes and in the formal reactive cellular arrangement of the proliferating tissue elements. There is also, as a rule, very marked eosinophilia of the local inflammatory cell infiltration. The final stage is one of connective tissue induration. Dr. Ziegler differentiates three different types: in the first two there is an increasing disappearance of the lymphatic cellular elements with a simultaneous proliferation of the connective tissue cells. In one form there is marked leucocytic infiltration; in the other it is entirely absent. The third type is characterised by pure lymphatic cell proliferation. These changes are examined in great detail by Dr. Ziegler, who also gives an interesting review of the etiology of the disease, and of the various agents, such as bacteria, spirochætæ, and Much's rods, which have been regarded as possible causal agents. He also discusses the diagnosis, prognosis, and treatment of the disease. He refers to the various methods of giving arsenic, including the injection of atoxyl and salvarsan. Operative and X ray treatment are also considered. A very full bibliography completes a valuable and interesting monograph upon this obscure and puzzling disease.

TREATMENT OF LEPROSY IN EGYPT.

THE Census of 1907 made the somewhat alarming discovery that there are more than 6000 lepers in Egypt, which is a number at least double that which has previously been mentioned in official figures. The Public Health Department has not yet devoted much time or study to this question, and there are as yet no laws upon the subject. But we are glad to see in the last annual report of that department that it is suggested that beggars and vagabonds affected with leprosy should be isolated, and that lepers should not be allowed to make or sell cigarettes and certain foods, nor should a leper be permitted to be an indoor servant or cook. With regard to treatment, as we remarked in our issue of June 3rd, chaulmoogra oil, among other remedies, has been tried and found wanting, so far as the cure of the disease is concerned, although it is useful for the alleviation of symptoms. There seems to be a consensus of opinion on this point. Dr. Engel, the German Director of Statistics of the Public Health Department of Egypt, and one of the few people in that country who for years have been interested in leprosy, however, has found chaulmoogra oil the most valuable remedy for leprosy. But as many patients were unable to continue its use he obtained a purified form of the oil, sold under the name of "anti-léprol," which is a clear limpid oil, with hardly any smell and

without disagreeable taste, and, moreover, without the secondary ill-effects, such as loss of appetite and indigestion, which chaulmoogra oil so often causes. He praises antiléprol highly, and finds that it is useful in both the nodular and nervous types of the disease. It is best prescribed in progressive doses, from 30 to 60 drops daily after meals in hot milk, and can be given in capsules. Children take half the dose of adults, and smaller amounts have to be given to a few people who seem unable to take it in ordinary doses. During the whole length of treatment, which may have to extend over three or more years, the patients must take care of their digestion, and must avoid salted food, such as fish, cheese, and vegetables. Dr. Engel now reports[1] the result of his treatment of 72 individuals, two-thirds of whom live in Cairo or in the adjacent provinces, and adds to his pamphlet several photographs of Egyptian lepers, some of which show slight amelioration after the use of the drug. His chief object in writing is to persuade the Wakfs Administration, who have sometimes been called the Ecclesiastical Commissioners of Egypt, to build a hospital for lepers where many out-patients can continue to be treated and a certain amount of police inspection might be instituted. In the interest of Egypt we hope that this may be done.

PARALYSIS OF THE LEFT RECURRENT LARYNGEAL NERVE IN MITRAL STENOSIS.

SINCE paralysis of the left recurrent laryngeal nerve was first described by Ortner in 1897 37 cases have been recorded. The notes of those cases in which a necropsy was performed show much difference of opinion as to the cause of the paralysis. In the *American Journal of the Medical Sciences* for May Dr. G. Fetterolf and Dr. G. W. Norris have given the results of a careful investigation made in order to clear up the discrepancies. Their work consisted in an analysis of all the published cases and an examination of sections of hardened thoraces. Observations were not made on soft bodies because the opening of the chest allows so much collapse and the manipulations of dissection cause so much distortion that normal relations are much altered. Ortner reported two cases and ascribed the paralysis to compression of the nerve between the arch of the aorta and the distended left auricle. He found the nerve discoloured, compressed, and ribbon-like. In the following year Herrick recorded a case in which, in addition to a dilated left auricle, there was chronic adhesive pericarditis, the nerve being embedded in a mass of cicatricial tissue as well as compressed by the auricle. In 1901 Krause reported a case. He took exception to Ortner's explanation, and concluded that the paralysis, though associated with dilatation of the left auricle, was indirectly due to hypertrophy of the left ventricle, which by changing the position of the heart as it lay on the diaphragm altered the relation between the pulmonary artery, the aortic arch, and the aortic ligament in such a way as to cause the ligament to drag on the recurrent nerve. In other cases the nerve is described as compressed between a patulous ductus arteriosus and the aortic arch, between the left pulmonary artery and the aorta (the former being pushed up by the dilated auricle), and between the dilated pulmonary artery and the aorta, and finally as pressed upon by enlarged peribronchial and peritracheal glands. As the result of their anatomical studies Dr. Fetterolf and Dr. Norris conclude that the left auricle can expand readily in but one direction—upwards; posteriorly it rests against the aorta and œsophagus; anteriorly it is limited by the right auricle and left ventricle, and below by the right auricle and liver. Should it become dilated it would press upward and backward, thrusting the left pulmonary artery against the aorta, the left pulmonary vein against the left pulmonary artery, and forcing the distal portion of the latter against the aorta. Later the proximal part of the left pulmonary artery would be jammed upward and backward, mainly by the root of the left upper pulmonary vein. The nerve would thus be squeezed between the pulmonary artery and the aortic arch or ligamentum arteriosum. But direct pressure of any portion of a dilated left auricle on the aortic arch is impossible. When the softness of all the structures involved is considered, as well as the fact that the nerve is normally flattened against the aorta, it seems probable that the paralysis is not due to destruction of the nerve by pressure but to neuritis so excited. In the absence of a necropsy reports of cases of recurrent paralysis in mitral stenosis due to auricular pressure should be received with scepticism, for, as stated above, the paralysis may be due to other causes such as the pressure of enlarged glands.

[1] Professor Dr. Engel Bey: Traitement de la Lèpre, Munich, 1910.

THE PRISON COMMISSION OF SCOTLAND.

WE have been informed that one of the Commissioners of the Scottish Prison Commission is about to retire, and we take the opportunity of pointing out how strong the arguments are that, if any vacancy should occur, it should be filled by a medical man. A Grand Committee of the House of Commons, a Departmental Committee of the Home Office, a Royal Commission on Irish Prisons, and a Scottish Departmental Committee on Prisons have all at different times pointed out the value of a medical voice at the deliberations of such a board; and a remarkable expression of opinion in the House of Commons last year proved that, in the opinion of the Legislature, the arguments for the creation of medical Prison Commissioners are very strong. Undoubtedly the presence of a medical commissioner greatly improves the administration of a Prisons Board, and increases the confidence of the public. We went into the whole matter recently when Mr. M. L. Waller, the possessor of only secretarial credentials, replaced Sir Horatio B. Donkin on the English Prison Commission, and the need for a medical member upon these Commissions is greater now than ever since the passing of the Inebriates Act, for example, added to the duties of the bureau. It seems to us that it will be particularly unfortunate if a medical man is not appointed to any vacancy that may occur on the Scottish Prisons Board, for an opportunity will thus be lost of giving effect to an opinion very strongly held by responsible persons. On such boards medical views should be heard at first hand.

WE regret to learn of the death of Dr. Samuel Jones Gee, consulting physician to St. Bartholomew's Hospital, which occurred rather suddenly on August 3rd.

BRITISH MEDICAL BENEVOLENT FUND.

AT the July meeting of the committee grants amounting to £158 were made to 15 cases. As the current account already showed a deficit of £54 it was necessary to draw largely upon the reserves, and the committee looks forward with grave anxiety to the heavy demands which will be made upon the resources of the Fund during the next two or three months. Contributions are greatly needed and may be sent to the honorary treasurer, Dr. Samuel West, 15, Wimpole-street, London, W. Appended is an abstract of the cases relieved:—

Daughter, aged 54, of late L.R.C.P., L.S.A. Is a candidate for a pension from a charity and meanwhile helped by friends. Recently lost a brother who also helped. Relieved three times, £15. Voted £5.

Daughter, aged 31, of late L.R.C.P., L.S.A. Since death of father

14 years ago has supported herself as a general servant, waitress, &c., but has now broken down in health and is at a convalescent home. Asks for a little help for temporary maintenance after leaving the home. Voted £5.

M.R.C.S., aged 83. Has been incapacitated for several years and dependent on a son who is no longer able to help. Voted £5 and recommended to apply for an old-age pension.

Daughter, aged 54, of late M.R.C.S. Receives a home in return for services but cannot do much on account of a long-standing physical infirmity. Relieved three times, £15. Voted £5.

Daughter, aged 67, of late M.R.C.S. Has supported herself for many years by nursing but is no longer fit for work and is endeavouring to obtain a pension from another charity. Relieved twice, £24. Voted £12.

Daughter, aged 42, of late M.R.C.S. Is a trained nurse, but for some few years has suffered from chronic glaucoma and is now quite unable to earn a living. Relieved three times, £25. Voted £10.

Widow, aged 49, of M.R.C.S. Endeavours to support herself by a boarding house and has established a good connexion but has been obliged to incur heavy expenses owing to the illness of three of her children. Relieved once, £10. Voted £10.

Daughter, aged 30, of late M.D. Dub. Unable to support herself on account of continued ill-health and is dependent on her mother whose sole income is £30 a year. Relieved six times, £40. Voted £10.

Daughter, aged 64, of late M.R.C.S., L.R.C.P. No means and unable to maintain herself on account of mental deficiency. Relieved five times, £60. Voted £12.

Widow, aged 50, of M.B., C.M. Edin. Dependent on income of £20 a year and such profits as she can make by taking boarders during the summer. Seven children, three of whom earn nominal salaries. Relieved 12 times, £138. Voted £12.

Widow, aged 63, of L.R.C.P. Lond. Sole means of support a furnished house, which is at present unlet. Children unable to help. Relieved once, £12. Voted £12.

Daughter, aged 59, of late M.R.C.S. Was fairly provided for but lost her capital through the defalcation of a friend. Relieved seven times, £92. Voted £12.

M.R.C.S., aged 72. Practised in London for several years, but now has cataract in both eyes. Relieved once, £18. Voted £18.

Daughter, aged 68, of late M.R.C.S. Used to keep a school, but was obliged to give it up on account of failing health, and is now dependent on a brother who can ill afford to help. Relieved twice, £24. Voted £12.

Widow, aged 60, of L.R.C.P., L.R.C.S. Dub. Did maternity nursing for several years but is now nearly blind. No children. Relieved 17 times, £161. Voted £18.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns 8284 births and 4940 deaths were registered during the week ending August 5th. The revised estimate of the population of these towns in the middle of this year is 16,157,797 persons. The annual rate of mortality in these towns, calculated on this revised estimate, which had been equal to 11·8, 12·1, and 13·6 per 1000 in the three preceding weeks, further rose to 15·9 in the week under notice. During the first five weeks of the current quarter the annual death-rate in these towns averaged 13·1 per 1000, while in London during the same period the mean annual death-rate did not exceed 12·6 per 1000. The recorded annual death-rates in the 77 towns last week ranged from 7·5 in Tottenham and in Northampton, 8·0 in Stockton-on-Tees, 8·2 in Barrow-in-Furness, and 8·7 in Walthamstow, to 21·3 in Middlesbrough, 21·5 in Walsall and in Birmingham, 22·0 in Rhondda, and 23·6 in Aston Manor. The 4940 deaths from all causes in the 77 towns last week exceeded the number recorded in the previous week by no fewer than 730, and included 1340 which were referred to the principal epidemic diseases, against numbers increasing from 268 to 722 in the five preceding weeks. Of these 1340 deaths, no fewer than 1168 resulted from infantile diarrhœa, 57 from whooping-cough, 53 from measles, 40 from diphtheria, 14 from scarlet fever, and 8 from enteric fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases was equal to 4·3 per 1000, against 1·4 and 2·3 in the two preceding weeks. The deaths of infants under two years of age attributed to diarrhœal diseases in the 77 towns, which had increased from 70 to 533 in the five preceding weeks, further rose last week to 1168, and caused the highest annual rates of 7·4 in Bootle, Newport, and Cardiff, 7·5 in Rhondda, 7·9 in Warrington, 8·2 in Wigan, 8·8 in Birmingham, and 9·0 in Aston Manor. The deaths referred to whooping-cough, which had been 43, 52, and 56 in the three preceding weeks, numbered 57 last week; the highest death-rates from this disease were 1·0 in Newcastle-on-Tyne, 1·1 in Wolverhampton, 1·4 in Sunderland, 1·6 in West Hartlepool, and 1·7 in Walsall. The 53 fatal cases of measles were 9 fewer than the number recorded in each of the two preceding weeks, and included 23 in London and its suburban districts, 7 in Manchester, 5 in Liverpool, and 3 in Salford and in Bolton. The deaths attributed to diphtheria last week numbered 40, against 40 and 42 in the two previous weeks, and included 8 in London, and 3 each in Stoke-on-Trent, Liverpool, Blackburn, and Leeds. The 14 fatal cases of scarlet fever showed a further decline upon recent weekly numbers, and included 4 deaths in Stoke-on-Trent, 3 in London, and 2 in Norwich. The 8 deaths from enteric fever were 3 fewer than the number in each of the two previous weeks; 2 deaths were registered in London. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had steadily increased from 982 to 1412 in the 16 preceding weeks, had further increased to 1433 on Saturday last; 191 new cases of this disease were admitted to these hospitals during the week, against 204, 199, and 209 in the three previous weeks. These hospitals also contained at the end of last week 854 cases of diphtheria, 286 of measles, 269 of whooping-cough, and 43 of enteric fever, but not one of small-pox. The 1344 deaths from all causes in London last week showed an increase of 159 upon the number returned in the previous week, and included 91 which were referred to diseases of the respiratory system, against 113 and 115 in the two previous weeks. The deaths attributed to different forms of violence in the 77 towns, which had declined from 194 to 173 in the three previous weeks, rose to 223 last week, and 412 inquest cases were registered. The causes of 33, or 0·7 per cent., of the deaths registered in the 77 towns during the week under notice were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death during last week were duly certified in Leeds, Bristol, West Ham, Bradford, Hull, Newcastle-on-Tyne, Portsmouth, Salford, and in 53 other smaller towns; the 33 uncertified causes of death in the 77 towns last week included 9 in Birmingham, 5 in Liverpool, 3 in Stoke-on-Trent, and 2 each in Manchester, Sunderland, and South Shields.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns, having an estimated population of 1,710,291 persons in the middle of this year, 866 births and 452 deaths were registered during the week ending August 5th. The annual rate of mortality in these towns, which had been 13·9 and 14·9 per 1000 in the two preceding weeks, declined last week to 13·8. During the first five weeks of the current quarter the annual death-rate in these Scotch towns averaged 14·4, and was 1·3 per 1000 above the mean rate during the same period in the large English towns. The annual death-rates in the eight Scotch towns last week ranged from 7·3 and 8·6 in Perth and in Paisley to 15·4 in Glasgow and 18·7 in Greenock. The 452 deaths from all causes in the eight towns last week showed a decrease of 36 from the number in the previous week, and included 62 which were referred to the principal epidemic diseases, against 63 and 73 in the two previous weeks; of these 62 deaths, 33 resulted from diarrhœa, 11 from measles, 7 from whooping-cough, 6 from diphtheria, 3 from enteric fever, 1 from scarlet fever, and 1 from small-pox. The mean annual death-rate from these epidemic diseases in the eight towns last week was equal to 1·9 per 1000, the mean rate last week from the same diseases in the 77 English towns having been 4·3. The deaths from diarrhœa, which had increased from 14 to 40 in the four preceding weeks, declined to 33 last week, and included 26 of infants under two years of age; 17 deaths occurred in Glasgow, 5 in Leith, 4 in Edinburgh, 3 in Dundee, and 3 in Greenock. The fatal cases of measles, which had been 6, 9, and 4 in the three previous weeks, rose to 11 last week, and included 9 in Glasgow. The deaths attributed to whooping-cough, which had been 17 in each of the two preceding weeks, declined last week to 7; 6 deaths were recorded in Glasgow and 1 in Aberdeen. The three deaths referred to enteric fever were slightly in excess of the numbers returned in recent weeks and were all recorded in Glasgow. The fatal case of scarlet fever was registered in Glasgow and that of small-pox in Dundee. The deaths referred to diseases of the respiratory system in the eight towns, which had been 51 and 48 in the two preceding weeks, declined to 32 in the week under notice, and were 27 below the number in the

corresponding week of last year. Of the 452 deaths from all causes in the eight towns last week, 153, or 34 per cent., were recorded in public institutions, and 31 were attributed to different forms of violence. The causes of 17, or 3·8 per cent., of the deaths in the eight towns last week were not specified or not certified; in the 77 English towns the proportion of uncertified causes of death during the week did not exceed 0·7 per cent.

HEALTH OF IRISH TOWNS.

The annual rate of mortality in Dublin, which had been 19·8 and 22·5 per 1000 in the two preceding weeks, declined to 18·9 during the week ending August 5th. During the first five weeks of the current quarter the death-rate in Dublin averaged 19·2 per 1000, whereas the mean rate during the same period did not exceed 12·6 in London and 15·3 in Edinburgh. The 146 deaths of Dublin residents from all causes last week showed a decrease of 28 from the number returned in the previous week, and included 41 which were referred to the principal epidemic diseases, against 22 and 48 in the two previous weeks. These 41 deaths were equal to an annual rate of 5·3 per 1000, the death-rate from the same epidemic diseases last week being equal to 4·2 in London and 1·0 in Edinburgh. Of the 41 deaths from these epidemic diseases in Dublin last week, 29 resulted from infantile diarrhœa, 5 from measles, 4 from whooping-cough, 2 from enteric fever, and 1 from scarlet fever, but not one from diphtheria or from small-pox. The deaths attributed to infantile diarrhœa, which had increased from 4 to 34 in the four preceding weeks, declined to 29 in the week under notice, while the deaths from the remaining epidemic diseases showed but slight variation from the numbers recorded in recent weeks. The 146 deaths at all ages included 53 of infants under one year of age, and 23 of persons aged upwards of 65 years; the deaths of infants were 7 in excess of the number in the previous week, while those of aged persons showed a decline of 12. Of the total deaths 37, or 25 per cent., occurred in public institutions. The causes of 3, or 2·1 per cent., of the total deaths last week were not certified; in London all but one of the causes of death were duly certified, while in Edinburgh the proportion of uncertified and unspecified causes of death amounted to 2·5 per cent. In the City of Belfast the death-rate during the week ending August 5th was equal to 16·6 per 1000, against 16·3 and 14·2 in the two preceding weeks. The 123 deaths from all causes included 25 which were referred to the principal epidemic diseases, against 22 and 24 in the two previous weeks. These 25 deaths were equal to an annual rate of 3·4 per 1000, and included 21 from infantile diarrhœa, 2 from whooping-cough, and 2 from diphtheria. All the causes of death in Belfast last week were duly certified, and 39, or 32 per cent., of the total deaths occurred in public institutions.

THE SERVICES.

ROYAL ARMY MEDICAL CORPS.

THE undermentioned Majors to be Lieutenant Colonels:—Thomas McCulloch, vice Sir J. Fayrer, Bart., retired (dated July 29th, 1911); John Ritchie, vice T. H. F. Clarkson, retired (dated July 29th, 1911); Stuart Macdonald, vice D. M. Saunders, retired (dated 29th July, 1911); Maurice P. C. Holt, D.S.O., vice H. W. Austin, retired (dated July 29th, 1911); William L. Gray, vice G. W. Brazier Creagh, retired (dated August 2nd, 1911); and Edward G. Browne, vice D. Hennessy, retired (dated August 2nd, 1911).

The undermentioned Captains to be Majors (dated July 27th, 1911):—William A. Woodside, Littleton F. F. Winslow, Otto W. A. Elsner, Arthur A. Seeds, Henry S. Anderson, Langford N. Lloyd, D.S.O., Thomas C. MacKenzie, D.S.O., Edward P. Connolly, James H. R. Bond, and Harold H. Norman.

Colonel T. J. R. Lucas, C.B., Principal Medical Officer of the Jhansi and Jubbulpore Brigades, has arrived home on leave of absence from India. Lieutenant-Colonel M. L. Hearn, at present serving in the Dublin District, has been placed under orders by the War Office for a tour of service in Ceylon. Major G. St. C. Thom, commanding the Station Hospital at Subathu, Simla District, has been granted one year's extension of his tour of service in India by H.E. the Commander-in-Chief. Major F. M. Parry has been placed under orders to proceed to Mauritius during the ensuing trooping season for a tour of foreign service. Major W. P. Gwynn has been transferred from Karachi to the Station Hospital at Quetta. Major T. MacDermott, specialist in ophthalmology at the Royal Herbert Hospital, Woolwich, has been selected to command No. 2 Cavalry Field Ambulance at the coming manœuvres on Salisbury Plain. Captain J. T. Johnson, from the Station Hospital at Bareilly, has taken up duty at Ranikhet. Captain H. C. Hildreth, from Dublin, has been placed in medical charge of the Artillery Camp at the Glen of Imaal. Captain J. M. B. Rahilly, on return from a tour of service in Egypt, has been appointed to the Woolwich District. An exchange on the roster of foreign service has been approved by the War Office between Captain M. F. Foulds, specialist in advanced operative surgery at Belfast, and Captain A. F. Carlyon, at present doing duty at the Military Hospital at Devonport. Captain R. E. U. Newman has been transferred from Rawal Pindi to the Military Hospital at Murree. Captain E. J. Kavanagh has joined the Station Hospital at Ranikhet from Delhi. Captain E. M. Middleton, from Amritsar, has been appointed to the Station Hospital at Rawal Pindi. Captain R. G. Meredith, on completion of a tour of foreign service at Malta, has been placed in Medical Charge of the Troops at Totley Camp. Captain A. A. Seeds, at present attached to the Military Hospital at Hounslow, has been placed under orders to proceed for a tour of duty with the Northern Army in India during the coming trooping season. Captain W. L. Baker and Captain R. J. C. Thompson have arrived home on leave from abroad. Captain G. W. G. Hughes has been appointed for duty in the Northern Command. Captain G. F. Sheehan, who is serving in India, has been appointed Specialist in Mental Science to the Northern Army. The following officers have been placed under orders by the War Office to proceed to India for a tour of service with the Southern Army during the coming trooping season: Lieutenant R. C. Prinst, Lieutenant R. C. Paris, Lieutenant A. W. Bevis, Lieutenant M. J. Williamson, Lieutenant M. White, and Lieutenant J. R. Yourell. Lieutenant W. J. Dunn, from Kirkee, has taken up duty at the Military Hospital, Colaba. Lieutenant R. O'Kelly has been transferred from the Bangalore Brigade to the Meerut Division and posted for duty with the Bareilly Brigade at Ranikhet. Lieutenant A. G. Jones, from the Military Hospital at Tidworth Park, has been placed in Medical Charge of the Artillery Camp at Lark Hill, Salisbury Plain. Lieutenant D. E. C. Pottinger, from Lucknow, has taken up duty at the Station Hospital, Bareilly. Lieutenant D. H. C. MacArthur has been transferred from Ambala Cantonment to the Military Hospital at Dagshai. Lieutenant J. A. Clark, from London, has joined for duty at Cairo.

INDIAN MEDICAL SERVICE.

The King has approved of the following promotions:—Lieutenant-Colonels to be Brevet Colonels (dated Jan. 1st, 1911): William Burney Bannerman and Henry Francis Cleveland. Captain to be Brevet Major (dated Jan. 1st 1911): Samuel Rickard Christophers.

The King has approved of the retirement of the undermentioned officers:—Surgeon-General Percy Hugh Benson (dated July 26th, 1911). Lieutenant-Colonel James Farquarson Maclaren (dated June 24th, 1911).

Lieutenant-Colonel W. R. Edwards, C.M.G., has been appointed by the Foreign Department of the Government of India to be Administrative Medical Officer of the North-West Frontier Province, in succession to Lieutenant-Colonel A. L. Duke, appointed to Baluchistan. H.E. the Governor of Bombay in Council has appointed Lieutenant-Colonel H. C. L. Arnim to officiate as Sanitary Commissioner for the Government of Bombay during the absence on deputation of Lieutenant-Colonel T. E. Dyson. Lieutenant-Colonel A. Coleman has relinquished charge of the duties of superintendent of the Multan District Jail to Captain W. W. Jeudwine. The services of Lieutenant-Colonel H. Hendley, civil surgeon of Lahore and professor of forensic medicine to the Government College at Lahore, have been placed at the disposal of the Government of India by the Punjab Administration. Lieutenant-Colonel C. H. Bedford, who has for several years been in charge of the Excise Laboratory at Kasauli as Chemical Expert, has been

granted leave of absence home from India for six months. Major E. D. W. Greig, assistant director of the Central Research Institute at Kasauli, has been granted eight months' leave of absence home from India. Major E. M. Illington has been transferred to Vizagapatam as Civil Surgeon and Superintendent of the Medical School. Major P. Dee, on return from leave, has been appointed Civil Surgeon at Mandalay, in succession to Major A. Fenton, transferred to Rangoon. Major H. S. Wood, on return from leave, has been appointed Civil Surgeon of the Rajshahai District. Captain C. G. Seymour has been appointed by H. E. the Commander-in-Chief as Specialist in the Prevention of Disease to the Dehra Dun Brigade, and has been placed in charge of the Bacteriological Research Laboratory at Dehra Dun. Captain L. B. Scott, on return from leave, has been appointed to Sylhet as Civil Surgeon. Captain H. Steen has joined for duty at the Presidency General Hospital at Calcutta during the absence on leave of Captain B. Foster. The services of Captain J. Kirkwood has been placed temporarily at the disposal of the Government of Madras. Lieutenant I. H. Bonnar has been appointed Civil Surgeon of the Garo Hills District.

TERRITORIAL FORCE.

Royal Army Medical Corps.

5th London Field Ambulance, Royal Army Medical Corps: Lieutenant William C. Macaulay to be Captain (dated June 13th, 1911).

Attached to Units other than Medical Units.—Lieutenant Frederick J. Green to be Captain (dated April 11th, 1911). Captain Edmund E. Dyer to be Major (dated July 5th, 1911).

For Attachment to Units other than Medical Units.—Arthur Edward Gladstone to be Lieutenant (dated May 16th, 1911). John Brabant Bate to be Lieutenant (dated June 17th, 1911).

The Southern General Hospital, Royal Army Medical Corps.

The 4th Southern General Hospital, Royal Army Medical Corps, has just completed the 15 days' annual training at the Military Hospital, Devonport. The camp consisted of two officers and 32 non-commissioned officers and men, with Major H. W. Webber and Lieutenant W. H. Scrase. Lieutenant-Colonel C. E. Russell Rendle commanded the unit.—The 2nd Southern General Hospital, Royal Army Medical Corps, from Bristol is now at the Military Hospital, Devonport, for the annual course of training.

Correspondence.

"Audi alteram partem."

THE CHOLERA CLOUD ON THE CONTINENT.

To the Editor of THE LANCET.

SIR,—While anxious to avoid creating any unnecessary alarm, may I say that it will be unpardonable neglect if sanitary authorities ignore the early symptoms indicating the possibility of a general outbreak of cholera. The fact that the Seventh International Congress of Dermatology and Syphilology and the Seventh International Congress on Tuberculosis which were to meet at Rome next September have been postponed is in itself a sufficiently serious matter. The Congress on Tuberculosis would have been a particularly important event. The preceding Congress met at Washington in the United States three years ago and some 6000 members attended. Among these no less than 800 came from Europe. Some members living in remote colonies and intending to attend the Congress at Rome have by this time left their homes, and one delegate from New Zealand has already arrived. To disappoint these distant travellers and to put off a congress of such importance is only justifiable in the face of some grave danger. Certainly, to judge from the cases of cholera reported during the last few weeks, they have nearly all come from Italy. Though occurring at Trieste, Gratz, Vienna, Marseilles, the patients had arrived from Italy. Even on the other side of the Atlantic the ships that have been detained at the New York quarantine station had travellers on board who came from Italy and who seemed to be, or in some cases actually were, suffering from cholera.

It is not necessary, however, for cholera to spread in Italy before the other western nations of Europe may consider themselves menaced. In Russia, it is true, the cholera has prevailed for several years without affecting the west of Europe, but it has now reached Constantinople, and from thence has travelled westwards to Bulgaria and Roumania, cases having occurred at Sofia and Bucharest. A Constantinople telegram dated August 2nd states that 43 cases of cholera and 22 deaths had occurred in that town within the previous 48 hours. If correct, such figures mean a great deal more than what we frequently hear about a few sporadic cases that generally occur during the hot weather. Thus there is no disguising the fact that we are once again exposed to the risk of a widespread outbreak such as occurred in 1892 and 1893.

There should be, however, an all-important difference. During the 18 or 19 years that have elapsed very great improvements have been effected. It is true the water fanatics rather discounted the moral teaching of the last epidemic. Important as it is to secure an ample and pure water-supply, this did not, and does not, suffice to prevent cholera epidemics. In 1907 there were published in THE LANCET an account and plans drawn to scale and photographs of certain slums which still remained at Hamburg.[1] These narrow, overcrowded courts had not been altered or improved notwithstanding the appalling havoc wrought in them during the epidemic of 1892. At Hamburg the water-supply was generally condemned as contaminated and this was altered promptly, elaborately, and at great expense. On the other hand, sufficient attention was not given to the fact that the cholera death-rate varied from 4·48 per 1000 inhabitants of the Harvestehude quarter to 27·50 per 1000 inhabitants of the Veddel quarter, though both these quarters of Hamburg received identically the same water-supply. So far as large towns were concerned, the most fatal epidemic after Hamburg was that of Havre, and here the water-supply was never suspected. On the contrary, some convincing statistics were published showing that it was not contaminated. But at Havre to-day, as at Hamburg, there still remain streets and courts, veritable fever dens, inviting all epidemics. At Havre, as at Hamburg, some of these danger centres have been pulled down, but some still remain standing. Therefore, all the danger is not dispelled. Something has been done, but not enough.

The extreme poor of most of our large cities still huddle together in overcrowded, dark, badly ventilated, dirty dwellings. Many more have not the excuse of extreme poverty. Their homes are insanitary because they are slovenly, indifferent, intemperate, incompetent, and idle in all matters of domestic management. Such a population is a culture ground for the cholera germ, and as long as all large cities can show a population of this kind, however small a section of the whole, we are not safe. To-day, in truth, everybody professes to believe in the necessity of sanitary measures and improvements. The difficulty remains, however, that epidemics are only prevented by far-reaching reforms, such as the draining of a district, the rebuilding of insanitary areas; and these public works cannot be carried out at the last moment when some urgent danger presses upon us. These things should be written about and spoken about when all is quiet, but it is just during those happy times of quietude that no one will listen. We must have a cholera epidemic, or a very close approach to one, before the general public will pay any real attention to the question. That science may know better does not help, for the needed reforms will not be efficacious nor will the money to pay for them be forthcoming unless the general public is quite convinced as to their necessity.

Nor is our civic morale yet all that it should be. Builders and speculators in unwholesome property still exist, and overcrowded tenement dwellings bring in large incomes to their owners; all of which means that many persons are actually interested in thwarting sanitary reform. At any rate they are willing that such changes as must be made should be made slowly. Hence it is not surprising that the obvious lessons to be derived from the cholera epidemics of 1892 and 1893 have not produced all the good expected from

[1] THE LANCET, Dec. 7th and 14th, 1907.

them at the time. The suffering, the dead, and the fear of death were forgotten too soon. Now perhaps an epidemic is upon us again, and it is too late to lament over the little use made of the 18 years of respite.

Of course, much has, as a matter of fact, been done, but not nearly so much as should have been done. To use a familiar simile, it is as if war had begun again. The early cases notified may be compared with the enemy's scouts and skirmishers who may be said to have crossed the frontier and invaded our part of Europe. Will they report that they have seen food for plunder and thus entice the main body to invade our lands; or will they return crest-fallen because they found everything so clean and in such good order that it did not seem worth while attempting a general attack? The cholera invasion of 1892 was not so successful as the previous outbreak of the same character, so perhaps this time the enemy may not venture on more than threats such as those recorded above. Should this, fortunately, prove to be the case, it is to be hoped that the alarm raised will suffice to draw attention to the fact that many of the obvious lessons taught by the previous epidemic have not yet been fully applied.

I am, Sir, yours faithfully,

Fulham, August 8th, 1911. ADOLPHE SMITH.

A QUESTION IN EUGENICS.

To the Editor of THE LANCET.

SIR,—As an alienist physician and a teacher with a not inconsiderable experience of mental diseases, and being acquainted with the care of epileptics suffering from mental symptoms, I consider it to be my duty to offer advice to your correspondent (of July 29th) who desires to have his epileptic son of 12 sterilised to prevent his having children if he should live to a marriageable age.

Let me be certain about the actual state of this boy. Presumably there are no (or only slight) mental symptoms, for otherwise detention in a special institution under special treatment would meet the circumstances, whilst the epilepsy itself, although it would seem not to prohibit matrimony should the son reach his majority and then care to exercise his privileges, is yet of such a nature as to disqualify for the ordinary avocations of life and is non-traumatic. Altogether this opportunity to discuss a very vexed question in eugenics acknowledges that you are conscious of the "signs of the times," and it will certainly afford the medical profession and others the means of ascertaining views presented on both horns of a very difficult dilemma and upon a matter of great public importance.

In spite of the tendency on the part of Nature towards the normal, and in spite of the apparent disposition of the germinal molecules to sustain and reproduce under favourable conditions of selection what is healthy and normal, epilepsy in my opinion, and in that of others who have studied and written upon the subject, has been proved by irrefragable statistical evidence to be the most heritable of all the neuroses and of all mental diseases; that is to say, "pure" epilepsy, or even epilepsy associated with insanity, is more often the antecedent of epilepsy than is insanity of insanity; and this is probably known to your correspodent, who by his suggestion in regard to this disease *a fortiori* suggests the treatment for many other less prominent neuroses—thus proposing to extinguish or at any rate to endeavour to prevent the extension of epilepsy in his own descendants.

The first question is whether we, as doctors, are to consider ourselves bound mainly to do the best we can for the individual or whether our care is to be for the race, and possibly the view taken depends on the ethical standard accepted by each person who ventures upon advice. Personally I am strongly in favour of the individualist view, for I conceive the ethical end to be the "perfection" of our patient, and this in the most active, most moral, and most intelligent direction consistent with time, circumstances, and environment.

As to the legal and moral aspect, a father is morally bound—i.e., by custom, by family ties, and by blood relationship—to do the best in his power for his son (or daughter), because the solidarity of the family is the essential principle to be kept in view in any community, and parental responsibility must be uppermost for the head of the family. He is bound to sustain, to preserve, and to shield his son from harm, so that his son's mental and physical powers, whether limited or of the ordinary range, may develop to the greatest perfection, and so that he may derive from them the greatest use and happiness.

The question of operation (or according to some "mutilation") for mental deficiencies or bodily ailments, is, in my opinion, not one to be entertained by the father, for he is concerned only with fostering the directly self-preservative instincts of his offspring—speaking generally, those relating to his own livelihood—and not those remotely relating to posterity. Legally, therefore, he has no option, but I am not a lawyer, and to him posterity is an unrealisable responsibility; still, if the community should enforce such an ordinance as sterilisation for its own future welfare, which it is entitled to do, then the parent is bound to accede to such indirectly self-preservative rules as may be agreed. I have no doubt in my own mind that the race would greatly benefit in physique by such enactments, but possibly not equally so in moral and mental qualities, for I look upon the presence of human weakness as a moral appeal to the strong and as serving a useful purpose in the moral development of any people.

I should like to be informed at what limit—i.e., for what defects—are such mutilations to cease? Are such operations to apply only to epileptics or those who are insane, some of whom we know occasionally recover completely? If for these, then why not for inebriates and criminals, or those with cancerous or tubercular tendencies, or those who are predisposed to paralysis, and if for these, again, why not for other persons who may be deficient in other forms of self-control, those, for instance, who inordinately gratify appetite and passion, those who are wanting in thrift and other prudential considerations, or for that matter those who exhibit the unpardonable crime of political defection or for any other apostasy? Furthermore, who is to be the final arbiter? And is the father himself averse from being subjected to the operation to prevent the possibility of more epileptic descendants?

The treatment least trying to parents and most acceptable to the main body of opinion in this country would be the provision by the State (or the local authority), with the sanction of Parliament, of a "home" wherein such cases could be made busy and happy, in which their lives would be fully occupied with employment congenial and graded to their abilities, and where their health and pastime could be adequately supervised. In this direction alone, in my opinion, lies the best and only justifiable solution. We are as yet unprepared for the (?) moral effect of a large number of "sterilised" men (and, of course, women) in the community; and even the State of Indiana, U.S.A., where 700 such persons are already said to exist, is blenching at the prospect!

Let me, in conclusion, relate an experience. I once had the care of a young medical man who had been the favourite pupil and "interne" of one of the physicians to the late Queen Victoria. He developed delusions, under the influence of which he so mutilated himself that he removed the whole of the external genitalia. Later, he sank into a state of unambitious passivity, without the desire or the capacity to originate conversation or to heed his surroundings. His mental state was that of careless and listless indifference to outward stimuli. He could occasionally be roused by questions referring to his past life, but he took no interest in the present or the future, which was beyond the power of any appeal to effort or action. He lounged or sat about, a slovenly inert wreck, dishevelled, self-neglectful, untidy, and personally disordered—a state of living death worse than could happen to the average epileptic who not infrequently enjoys a useful interparoxysmal life. That such a state was partly the result of sex "mutilation" admits of no doubt in my mind, and such reducing mental consequences of "restrictive" eugenics must not be overlooked. I am strongly of opinion, after consultation with the titular heads of the medical profession, that suggestions in regard to sterilisation are at the present moment premature and would not be tolerated. They have no moral support and certainly, at present, they have no legal justification.

I am, Sir, yours faithfully,

Claybury, August 3rd, 1911. ROBERT JONES, M.D. Lond.

To the Editor of THE LANCET.

SIR,—The sterilisation of the unfit is legalised in the State of Indiana and also in Switzerland. In the former several hundreds of cases have been performed with very successful

results, but so far as I know eugenic sterilisation has never been done in Great Britain. Assuming, however, that the law permits it, in my opinion a surgeon would be morally right in acceding to the request of the parent who desired that an epileptic child should be sterilised. Nay, I would go further, and after careful delving into the family history, should it be apparent that there is some morbid flaw in the mosaic of the germ plasm of the parents, I would strongly advise that they also should be sterilised if still capable of producing offspring. The method which should be adopted is most important. Castration is crude and brutal; X rays uncertain and inefficient; the simplest, the best, and the most permanent would be vasectomy, which makes no difference to the bodily functions, has no ill-effects, secondary sexual characters would be developed, and nothing would be prevented but the power of procreation.

The answer to the question depends upon whether you regard the rights of the individual as absolute and the claims of the race as non-existent. If you do, sterilisation will be an accursed thing; if not, it will be gladly welcomed. As marriage is the supreme eugenic institution, why should an epileptic child be permitted to grow up, marry, and produce offspring suffering from physical and mental defects? Is marriage the intimate personal affection, the spiritual tie, the indissoluble union, which purifies the passions of the sexes and raises us above the level of the beasts? Is marriage for the sake of parentage and parentage a trust for the race? Must we be ever satisfied that the ghastly burden of disease of body and mind should be freely transmitted from age to age and no steps be taken to dam the overflow of this reeking cesspool? Should we leave open the flood-gates through which has poured a devastating torrent of degraded humanity? Mr. Roosevelt has said "A nation's chief blessing was that it should leave its seed to inherit the land. No refinement of life, no delicacy of taste, no material progress, no sordid keeping up of riches, no sensuous developments of art and literature, can in any way compensate for the loss of the great fundamental virtues, and of these great fundamental virtues the greatest is the race's power to perpetuate the race." Ruskin stated that the veins of wealth are purple and that the Divine intent of all wealth is the production of a healthy race.

The unfit should have the right to live, and live well—no one will question that—but the right to propagate should be denied them. The average quality of a race is but the average quality of the individuals composing it. If the physically and mentally weak be allowed to propagate, and if, as it seems to be the case at present, they reproduce themselves faster than the better strains, the relative numbers of such persons in the country must increase and the average quality of the race deteriorate. The best stocks are postponing marriage and restricting the number of their offspring. The latter are producing motor-cars, the former children.

> "Better, oh better, cancel from the scroll
> Of universe one luckless human soul,
> Than drop by drop enlarge the flood that rolls
> Hoarser with anguish as the ages roll."—FITZGERALD.

I am, Sir, yours faithfully,

Claybury, August 1st, 1911. C. T. EWART, M.D. Aberd.

SALVARSAN ("606") AND MERCURY IN THE TREATMENT OF SYPHILIS.

To the Editor of THE LANCET.

SIR,—In to-day's LANCET (July 29th) Major H. C. French, R.A.M.C., replies to the criticisms of myself and others on his paper on this subject that appeared in THE LANCET of June 24th. The party system in politics, by insuring searching criticism, gives the country the opportunity of arriving at an unbiassed opinion on the questions at issue; and likewise with any new therapeutic agent it is essential that adverse critics should be found to lay before the medical public all the possible evidence against the new treatment. The medical profession must always be equally indebted to the opponents and advocates of any new "specific."

Major French observes the rules of debate and with courtesy replies to criticism, and it is a matter of regret that Mr. Ernest Lane makes no attempt to reply to my criticism of his published opinion. Mr. Lane has apparently changed his mind in regard to the danger and value of salvarsan treatment, and makes it a grievance that I should have thought that he meant what he said in December last, which I quoted as the only record of his opinion that I can find. Major French quotes me as writing in support of the great value of inunctions and injections of mercury as shown by the Wassermann reaction. I am sorry that he thought my advocacy of salvarsan meant detraction of mercury. That this is not my view is shown by the paper that I wrote with Dr. A. Manuel in the *Practitioner* for June, where we concluded that "salvarsan when it does produce an alteration of the serum reaction does so more rapidly than mercury. On the other hand, in the present state of our knowledge it would appear that the percentage of negative results after one or two injections is lower than that observed after a year's course of efficient mercurial treatment." The Wassermann reaction frequently becomes negative after one or two courses of inunction or injection, but these negative reactions are rarely permanent, whereas after salvarsan apparently about 75 per cent. of cases that become negative as the result of such treatment remain so.

I am entirely in accord with Major French's quotation of Mr. Boas's opinion as to the superiority of Wassermann's original technique and the importance of *quantitative* estimations. My modifications are solely trifling matters of technique, with the exception that I use alcoholic extract of rabbit's heart in place of alcoholic extract of syphilitic organs. I have made parallel experiments, using rabbit's heart extract and syphilitic organ extract supplied from Professor Wassermann's own laboratory, and have obtained practically identical results with both, the very slight difference being in favour of the heart extract. At the British Medical Association discussion on the Diagnostic Use of the Complement Fixation Method that took place in July, 1910, and was opened by a paper from Professor Wassermann, I had the honour of reading the second paper. I then said[1]: "Many observers have tried to simplify the test and obviate the necessity for using rabbits and guinea-pigs by making use of the complement and hæmolysin for sheep's corpuscles present in human blood serum. It seems to me, however, that the most essential of all factors in a comparative test such as this is that all factors except the one to be tested should be constant. With Hecht's, Bauer's, Stern's, or Fleming's technique, however, variants are substituted for constants, for the complement content of human serum varies greatly, and some human serums contain no hæmolytic antibody to sheep's corpuscles, while others contain some but in varying quantities." Later on I said: "I have for the last six months used two strengths of complement and so obtained a roughly quantitative measurement of the complement deviating power of the serum." In a footnote I wrote: "This quantitative measurement can obviously not be determined by the so-called simplified methods."

In the *Quarterly Journal of Medicine* for January, 1911, I wrote: "It is remarkable that though innumerable modifications and simplifications have been introduced during the last two years, the consensus of expert opinion is still strongly in favour of the original technique, or of such slight modifications of the original method as do not necessitate the substitution of variant factors for constant factors." Major W. S. Harrison, R.A.M.C., agrees with me that the original technique is the most reliable, and probably Major Harrison and myself have greater opportunities for extended investigations on this subject than other workers in this country. I have personally examined well over 2000 sera, and as a matter of routine determine the reaction in about 30 cases every week. I am cordially in sympathy with Major French's opinion as to the necessity for standardising the test, and on Dec. 2nd, 1910, said: "I am entirely in accord with Mr. Arthur Shillitoe in desiring the universal adoption of the same technique for the Wassermann reaction."[2]

The points I wished to emphasise were: (1) the extremely small casualty *proportion*, which, being less than 0·2 per cent. even in the early days, is almost negligible; and (2) that salvarsan should be given as a routine in all cases except the very exceptional ones when it is contra-indicated. These points I do not think have been satisfactorily met by Major French and have been ignored by Mr. Lane. I do not suggest, and never have suggested, that the time has yet arrived when mercury can be dispensed with in

[1] Brit. Med. Jour., Nov. 5th, 1910, p. 1430.
[2] West London Medical Journal, January, 1911, p. 48.

every case; on the contrary, I think that there is a large percentage where mercury is indispensable.

I am, Sir, yours faithfully,

HUGH WANSEY BAYLY.

Upper Berkeley-street, July 29th, 1911.

To the Editor of THE LANCET.

SIR,—In THE LANCET of July 29th Major H. C. French states that it is impossible to carry out the Wassermann reaction quantitatively by any of the ordinarily suggested modifications. May I point out to you that this is not only possible, but very easy, on the process which I have elaborated and which I described in my second Hunterian lecture?[1] I have now used the method constantly, almost daily, for a year and am absolutely satisfied with it, both as regards its simplicity and quickness and as regards the clinical value of its results. I have, however, found it convenient to alter the strength of my antigen so that a reaction given with a dilution of 1 in 10 is to be regarded as a positive, though weak, reaction. I should like to call especial attention to the method, since I quite agree as to the great importance of performing the test quantitatively, and this is the only process by which it can be done with ease, rapidity, and accuracy.

I am, Sir, yours faithfully,

Harley-street, W., August 9th, 1911. W. D'ESTE EMERY.

THE ADMINISTRATIVE CONTROL OF TUBERCULOSIS.

To the Editor of THE LANCET.
